Lead Agency Contact:

Robert R. Kulikowski, Ph.D.

Project Applicant:

Queens Development Group, LLC

August 2013

Willets Point Development
FINAL SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT
(FSEIS)

Project Location: Willets Point / CitiField Parking Lots
Borough of Queens
The Willets Point portion of the site (east of 126th Street) is located within Community District 7; the remainder of the project site comprising CitiField parking lots is mapped parkland and lies outside community district boundaries.

CEQR No. 07DME014Q

Type of Action: Type I

ULURP Nos. N130220ZRQ
N130222ZSQ
N130223ZSQ
N130224ZSQ
N130225ZSQ
M080221(A)MMQ

Lead Agency: Office of the Deputy Mayor for Economic Development

Lead Agency Contact: Robert R. Kulikowski, Ph.D.

Project Applicant: Queens Development Group, LLC

Preparers: AKRF, Inc.
Vanasse Hangen Brustlin, Inc.
S9 Architecture and Engineering, PC
Langan Engineering & Environmental Services, Inc.
Integral Consulting, Inc.
Fox Rothschild, LLP
Stroock & Stroock & Lavan LLP

Acceptance Date: August 2013

The FSEIS is available for review on the website of the Mayor's Office of Environmental Coordination.

Table of Contents

Foreword.....	F-1
Executive Summary	S-1
1: Project Description	1-1
A. Introduction.....	1-1
B. Project Background.....	1-1
Prior Environmental Review	1-2
C. Project Description.....	1-4
Site Description	1-4
Goals and Objectives.....	1-5
Proposed Project.....	1-5
Purpose and Need.....	1-9
Discretionary Actions Subject to CEQR and SEQRA	1-9
D. Analytical Framework for Environmental Review	1-10
Overview	1-10
Study Areas	1-11
Future Analysis Year and Baseline Conditions.....	1-12
2: Land Use, Zoning, and Public Policy	2-1
A. Introduction.....	2-1
Principal Conclusions.....	2-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	2-2
C. Methodology	2-2
D. Existing Conditions	2-3
Land Use	2-3
Zoning	2-13
Public Policy	2-17
E. The Future Without the Proposed Project	2-21
Land Use	2-21
Zoning	2-26
Public Policy	2-26
F. Probable Impacts of the Proposed Project.....	2-26
Land Use	2-27
Zoning	2-33
Public Policy	2-34
G. Waterfront Revitalization Program	2-36
Consistency of Proposed Project With the Waterfront Revitalization Program Policies.....	2-36

3: Socioeconomic Conditions	3-1
A. Introduction	3-1
Principal Conclusions	3-1
B. Summary of Findings, 2008 FGEIS and Subsequent Technical Memoranda	3-5
Direct Residential Displacement	3-5
Direct Business and Institutional Displacement	3-5
Indirect Residential Displacement Due to Increased Rents	3-5
Indirect Business and Institutional Displacement Due to Increased Rents	3-6
Indirect Business Displacement Due to Competition	3-6
Adverse Effects On Specific Industries	3-7
C. Methodology	3-7
Background	3-7
Determining Whether A Socioeconomic Assessment Is Appropriate	3-8
Analysis Format	3-10
Study Area Definition	3-10
Data Sources	3-11
D. Update On Direct Business Displacement	3-12
E. Preliminary Assessment	3-13
Indirect Residential Displacement	3-14
Indirect Business Displacement Due to Increased Rents	3-16
Indirect Business Displacement Due to Retail Market Saturation	3-20
F. Detailed Analysis of Indirect Residential Displacement	3-31
Existing Conditions	3-31
The Future Without the Proposed Project	3-38
Probable Impacts of the Proposed Project	3-39
G. Detailed Analysis of Indirect Business Displacement Due to Retail Market Saturation	3-41
Existing Conditions	3-42
The Future Without the Proposed Project	3-47
Probable Impacts of the Proposed Project	3-48
 4: Community Facilities and Services	 4-1
A. Introduction	4-1
Principal Conclusions	4-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	4-2
C. Preliminary Screening	4-3
Direct Effects	4-4
Indirect Effects	4-4
D. Indirect Effects On Public Elementary, Intermediate, and High Schools	4-6
Methodology	4-6
Existing Conditions	4-7
The Future Without the Proposed Project	4-8
Probable Impacts of the Proposed Project	4-8
E. Indirect Effects On Libraries	4-13
Methodology	4-13
Existing Conditions	4-14
The Future Without the Proposed Project	4-14
Probable Impacts of the Proposed Project	4-15
F. Indirect Effects On Child Care Services	4-17

Methodology	4-17
Existing Conditions	4-18
The Future Without the Proposed Project	4-18
Probable Impacts of the Proposed Project.....	4-19
G. Health Care Facilities	4-20
Methodology	4-20
Existing Conditions	4-20
The Future Without the Proposed Project	4-22
Probable Impacts of the Proposed Project.....	4-23
H. Police and Fire Protection Services.....	4-24
Police Protection Services	4-24
Fire Protection Services	4-26
5: Open Space.....	5-1
A. Introduction.....	5-1
Principal Conclusions.....	5-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	5-3
C. Methodology	5-3
Analysis Approach	5-3
Direct Effects Analysis.....	5-3
Indirect Effects Analysis	5-4
Study Areas	5-4
Study Area Populations.....	5-5
Inventory of Open Space Resources	5-5
Adequacy of Open Space Resources.....	5-6
D. Existing Conditions	5-7
Study Area Population	5-7
Study Area Open Spaces	5-8
Adequacy of Open Spaces.....	5-11
E. The Future Without the Proposed Project	5-13
2018.....	5-13
2028.....	5-16
2032.....	5-17
F. Probable Impacts of the Proposed Project.....	5-17
Direct Effects.....	5-17
Indirect Effects	5-19
Impact Significance.....	5-23
6: Shadows.....	6-1
A. Introduction.....	6-1
Principal Conclusions.....	6-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	6-1
C. Definitions and Methodology	6-2
Definitions.....	6-2
Methodology	6-2
D. Preliminary Screening Assessment	6-4
Tier 1 Screening Assessment	6-4
Tier 2 Screening Assessment	6-4

Willets Point Development

Tier 3 Screening Assessment.....	6-5
E. Detailed Shadow Analysis.....	6-6
March 21/September 21.....	6-7
May 6/August 6	6-7
June 21	6-7
December 21.....	6-7
F. Conclusions	6-7
7: Historic and Cultural Resources	7-1
A. Introduction	7-1
Principal Conclusions	7-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	7-1
C. Methodology.....	7-2
D. Existing Conditions	7-3
Project Site.....	7-3
Study Area	7-4
E. The Future Without the Proposed Project	7-4
Project Site.....	7-4
Study Area	7-4
F. Probable Impacts of the Proposed Project.....	7-5
Project Site.....	7-5
Study Area	7-4
8: Urban Design and Visual Resources	8-1
A. Introduction	8-1
Principal Conclusions	8-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	8-1
C. Preliminary Assessment	8-2
D. Methodology.....	8-3
E. Existing Conditions	8-4
Project Site.....	8-4
Visual Resources	8-10
F. The Future Without the Proposed Project	8-11
Project Site.....	8-11
Study Area	8-11
G. Probable Impacts of the Proposed Project.....	8-12
Urban Design	8-12
Visual Resources	8-18
9: Natural Resources.....	9-1
A. Introduction	9-1
Principal Conclusions	9-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	9-1
C. Methodology.....	9-1
Future Without the Proposed Project.....	9-2
Potential Impacts from the Proposed Project.....	9-2
D. Existing Conditions	9-3
Floodplains	9-3

Wetlands.....	9-4
Terrestrial Resources.....	9-4
Groundwater.....	9-5
Aquatic Resources.....	9-5
Threatened, Endangered, Rare, and Special Concern Species and Significant Ecological Communities	9-7
Essential Fish Habitat (EFH).....	9-7
E. The Future Without the Proposed Project	9-8
Terrestrial Resources.....	9-8
Aquatic Resources.....	9-9
F. Probable Impacts of the Proposed Project.....	9-10
Floodplains.....	9-10
Wetlands.....	9-11
Terrestrial Resources.....	9-11
Groundwater.....	9-14
Aquatic Resources.....	9-14
Threatened, Endangered, Rare, and Special Concern Species and Significant Ecological Communities	9-15
Essential Fish Habitat.....	9-15
G. References.....	9-15
10: Hazardous Materials	10-1
A. Introduction.....	10-1
Principal Conclusions.....	10-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	10-3
Special Willets Point District	10-3
Lot D and Lot B	10-5
C. Methodology	10-6
D. Existing Conditions.....	10-6
E. The Future Without the Proposed Project	10-7
F. Probable Impacts of the Proposed Project.....	10-7
Conclusions	10-9
Chapter 11: Water and Sewer Infrastructure.....	11-1
A. Introduction.....	11-1
Principal Conclusions.....	11-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	11-3
Water Supply.....	11-3
Sanitary Sewage	11-3
Stormwater	11-4
Combined Sewer Overflows	11-5
C. Methodology	11-5
D. Existing Conditions.....	11-5
Water Supply.....	11-6
Sanitary Sewage	11-7
Stormwater	11-9
Combined Sewer Overflows	11-10
E. The Future Without the Proposed Project	11-11

Water Supply	11-11
Sanitary Sewage.....	11-12
Stormwater.....	11-12
Combined Sewer Overflows.....	11-12
F. Probable Impacts of the Proposed Project	11-12
Phase 1A (2018)	11-12
Phase 1B (2028).....	11-18
Phase 2 (2032)	11-22
12: Solid Waste and Sanitation	12-1
A. Introduction	12-1
Principal Conclusions	12-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	12-1
C. Methodology.....	12-2
D. Existing Conditions	12-2
Sanitation Services.....	12-2
Solid Waste Generation	12-3
E. The Future Without the Proposed Project	12-4
F. Probable Impacts of the Proposed Project.....	12-5
RWCDs	12-5
13: Energy	13-1
A. Introduction	13-1
Principal Conclusions	13-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	13-2
C. Methodology.....	13-2
D. Existing Conditions	13-2
Energy Supply and Transmission	13-2
Energy Initiatives.....	13-3
Existing Demand	13-3
E. The Future Without the Proposed Project	13-4
F. Probable Impacts of the Proposed Project.....	13-4
Energy Demand With the Proposed Project	13-6
14: Transportation	14-1
A. Introduction	14-1
Principal Conclusions	14-2
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	14-5
C. Scope of Analysis (Traffic and Parking)	14-5
D. Existing Conditions (Traffic and Parking)	14-6
Roadway Network and Traffic Study Area	14-6
Existing Traffic Volumes and Levels of Service.....	14-11
Parking.....	14-24
E. The Future Without the Proposed Project (Traffic and Parking).....	14-30
No Action Background Projects	14-30
Phase 1A (2018) No Action Traffic Conditions	14-33
Phase 1A (2018) No Action Parking Conditions.....	14-38
Phase 1B (2028) No Action Traffic Conditions	14-39

Phase 1B (2028) No Action Parking Conditions.....	14-41
Phase 2 (2032) No Action Traffic Conditions.....	14-42
Phase 2 (2032) No Action Parking Conditions	14-44
F. Probable Impacts of the Proposed Project (Traffic and Parking).....	14-45
Trip Generation and Modal Split.....	14-46
Proposed Roadway Improvements	14-51
Trip Distribution and Assignment to the Roadway Network.....	14-52
Game Day Circulation Changes	14-54
Traffic Levels of Service and Significant Impact Criteria	14-55
Phase 1A (2018) Traffic Analysis Results	14-56
Phase 1A (2018) With Action Parking.....	14-63
Phase 1B (2028) Traffic Analysis Results	14-67
Phase 1B (2028) With Action Parking.....	14-74
Phase 2 (2032) Traffic Analysis Results	14-77
Phase 2 (2032) With Action Parking.....	14-87
G. Highway Network Analysis	14-91
Introduction and Methodology.....	14-91
Existing Conditions.....	14-93
Existing Levels of Service.....	14-94
The Future Without the Proposed Project	14-97
Phase 1A (2018) No Action Condition	14-98
Phase 1B (2028) No Action Condition.....	14-101
Phase 2 (2032) No Action Condition	14-105
Probable Impacts of the Proposed Project.....	14-109
Phase 1A (2018) With Action Conditions.....	14-110
Phase 1B (2028) With Action Conditions.....	14-114
Phase 2 (2032) With Action Conditions.....	14-119
H. Scope of Analysis (Transit and Pedestrians).....	14-124
Transit and Pedestrian Study Areas.....	14-124
Operational Analysis Methodology.....	14-126
I. Existing Conditions (Transit and Pedestrians)	14-131
Subway Station Operations	14-133
Subway Line Haul Levels	14-136
Bus Line Haul Levels.....	14-137
Street-Level Pedestrian Operations	14-138
J. The Future Without the Proposed Project (Transit and Pedestrians)	14-143
2018 No Action Condition	14-143
2028 No Action Condition	14-152
2032 No Action Condition	14-160
K. Probable Impacts of the Proposed Project (Transit and Pedestrians).....	14-168
2018 With Action Condition	14-168
2028 With Action Condition	14-181
2032 With Action Condition	14-193
L. Vehicular and Pedestrian Safety	14-204
114th Street and Roosevelt Avenue	14-210
Main Street and Northern Boulevard	14-211
Main Street and Roosevelt Avenue	14-211
Main Street and 41st Avenue/Kissena Boulevard	14-212

Union Street and Northern Boulevard	14-212
Union Street and Roosevelt Avenue	14-214
Parsons Boulevard and Northern Boulevard	14-214
M. Dual Event Conditions With U.S. Tennis Open	14-215
N. Potential Major League Soccer Stadium	14-215
Traffic and Parking	14-215
Transit and Pedestrians	14-220
15: Air Quality	15-1
A. Introduction	15-1
Principal Conclusions	15-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	15-2
C. Pollutants for Analysis	15-2
Carbon Monoxide	15-3
Nitrogen Oxides, VOCs, and Ozone	15-3
Lead	15-4
Respirable Particulate Matter—PM ₁₀ and PM _{2.5}	15-4
Sulfur Dioxide	15-5
Noncriteria Pollutants	15-5
D. Air Quality Regulations, Standards, and Benchmarks	15-5
National and State Air Quality Standards	15-5
NAAQS Attainment Status and State Implementation Plans	15-7
Determining the Significance of Air Quality Impacts	15-9
E. Methodology for Predicting Pollutant Concentrations	15-10
Introduction	15-10
Mobile Sources	15-10
Parking Facilities	15-16
Stationary Sources	15-17
F. Existing Conditions	15-21
G. The Future Without the Proposed Project	15-22
Mobile Sources	15-22
Stationary Sources	15-23
H. Probable Impacts of the Proposed Project	15-23
Mobile Sources Analysis	15-24
Parking Facilities	15-28
Stationary Sources	15-29
16: Greenhouse Gas Emissions and Climate Change	16-1
A. Introduction	16-1
Principal Conclusions	16-1
B. Summary of Findings, 2008 FGEIS and Subsequent Technical Memoranda	16-2
C. GHG Emissions	16-2
Policy, Regulations, Standards, and Benchmarks for Reducing GHG Emissions	16-2
Methodology	16-4
Projected GHG Emissions With the Proposed Project	16-6
Elements of the Proposed Project That Would Reduce GHG Emissions	16-9
Conclusions	16-12
D. Resilience to Climate Change	16-12

Development of Policy to Improve Climate Change Resilience	16-13
Resilience of the Proposed Project to Climate Change	16-15
17: Noise.....	17-1
A. Introduction.....	17-1
Principal Conclusions.....	17-1
B. Summary of Findings, 2008 FGEIS and Subsequent Technical Memoranda.....	17-2
C. Noise Fundamentals.....	17-2
“A”-Weighted Sound Level (dBA)	17-2
Ability to Perceive Changes in Noise Levels	17-3
D. Noise Standards and Criteria.....	17-4
New York City Noise Control Code	17-4
New York CEQR Noise Criteria	17-4
E. Impact Definition	17-4
F. Noise Prediction Methodology	17-6
General Methodology.....	17-6
Proportional Modeling	17-6
Traffic Noise Model (TNM).....	17-7
FTA Parking Lot/Garage Analysis Methodology	17-7
Analysis Procedure.....	17-7
G. Existing Conditions	17-8
Site Description	17-8
Selection of Noise Receptor Locations	17-9
Noise Monitoring	17-9
Equipment Used During Noise Monitoring	17-9
Existing Noise Levels At Noise Receptor Locations	17-10
H. The Future Without the Proposed Project	17-11
2018 Analysis Year	17-11
2028 Analysis Year	17-11
2032 Analysis Year	17-13
I. Probable Impacts of the Proposed Project.....	17-14
Phase 1A (2018).....	17-14
Phase 1B (2028)	17-14
Phase 2 (2032).....	17-15
J. Building Attenuation for Project Buildings	17-16
K. Noise Levels At Open Space Areas	17-18
L. Mechanical Equipment.....	17-18
18: Public Health.....	18-1
A. Introduction.....	18-1
19: Neighborhood Character	19-1
A. Introduction.....	19-1
Principal Conclusions.....	19-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda.....	19-1
C. Methodology	19-2
D. Preliminary Assessment	19-2
Defining Features	19-2

Potential to Affect Defining Features of A Neighborhood	19-8
20: Construction	20-1
A. Introduction	20-1
Principal Conclusions	20-3
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	20-5
C. Analysis Approach	20-7
D. Methodology.....	20-7
E. Construction Phasing and Activities.....	20-8
Introduction	20-8
Conceptual Construction Phasing and Schedule	20-8
Construction Description	20-12
Number of Construction Workers and Material Deliveries	20-23
F. The Future Without the Proposed Project	20-24
G. Probable Impacts of the Proposed Project	20-24
Transportation.....	20-25
Air Quality	20-36
Noise and Vibration.....	20-48
Other Technical Areas	20-57
21: Mitigation.....	21-1
A. Introduction	21-1
B. Community Facilities and Services	21-1
C. Historic and Cultural Resources	21-2
D. Traffic and Parking.....	21-2
Traffic—Phase 1A (2018)	21-3
Traffic—Phase 1B (2028).....	21-12
Traffic—Phase 2 (2032)	21-21
Highway Mitigation.....	21-31
Implementation	21-38
E. Transit and Pedestrians	21-62
Transit.....	21-62
Pedestrians	21-68
F. Air Quality.....	21-85
Effects of Proposed Traffic Mitigation Measures.....	21-85
G. Noise.....	21-90
H. Construction	21-91
Historic and Cultural Resources	21-92
Traffic	21-92
Transit.....	21-92
Pedestrians	21-92
22: Alternatives.....	22-1
A. Introduction	22-1
Principal Conclusions	22-1
B. Summary of Findings—2008 FGEIS and Subsequent Technical Memoranda	22-3
C. No Action Alternative	22-4
Description.....	22-4

Land Use, Zoning, and Public Policy	22-4
Socioeconomics.....	22-5
Community Facilities	22-6
Open Space.....	22-7
Shadows	22-7
Historic and Cultural Resources.....	22-8
Urban Design and Visual Resources	22-8
Natural Resources	22-8
Hazardous Materials.....	22-8
Water and Sewer Infrastructure.....	22-8
Solid Waste and Sanitation	22-9
Energy	22-9
Transportation	22-9
Air Quality.....	22-14
Greenhouse Gas Emissions and Climate Change.....	22-15
Noise	22-15
Public Health.....	22-15
Neighborhood Character	22-15
Construction	22-16
D. No Unmitigated Significant Impacts Alternative	22-16
Description	22-16
23: Unavoidable Significant Adverse Impacts.....	23-1
A. Introduction.....	23-1
B. Historic and Cultural Resources.....	23-1
C. Transportation	23-1
Traffic and Parking.....	23-1
Transit and Pedestrians.....	23-4
24: Growth-Inducing Aspects of the Proposed Project	24-1
A. Introduction.....	24-1
25: Irreversible and Irretrievable Commitment of Resources	25-1
26: Response to Comments Received on the DSEIS	26-1

Appendices

Appendix A-1: Proposed Zoning Text Amendment
Appendix A-2: WRP Consistency Assessment Form
Appendix B: Agency Correspondence
Appendix C: Traffic
Appendix D: Transit
Appendix E: Construction
Appendix F: Comments on the DSEIS

List of Tables

S-1	Summary of Proposed Program, By Phase	S-7
S-2	Proposed New and Replacement Parking (Cumulative By Phase)	S-8
S-3	Totals by Use in Special Willets Point District Proposed Program vs. 2008 FGEIS	S-8
S-4	Project Site Employment by Business Type and Sector December 2012	S-14
1-1	Summary of Proposed Program, By Phase	1-8
1-2	Proposed New and Replacement Parking (Cumulative By Phase)	1-8
1-3	Totals by Use in Special Willets Point District Proposed Program vs. 2008 FGEIS	1-9
2-1	Zoning Districts in Primary and Secondary Study Areas.....	2-13
2-2	No Action Projects	2-22
3-1	Project Site Employment by Business Type and Sector December 2012	3-3
3-2	Project Site Employment by Business Type and Sector As Reported in 2008 FGEIS	3-12
3-3	Project Site Employment by Business Type and Sector December 2012	3-13
3-4	Average Household Income (1999, 2007–2011).....	3-15
3-5	2000 and 2010 Population.....	3-15
3-6	Estimated Population in the ¾-Mile Study Area: 2032 No-Action and With-Action Conditions	3-16
3-7	Estimated Employees in ¾-Mile Study Area, Queens, and New York City 2011	3-17
3-8	Retail Sales in the Primary Trade Area	3-22
3-9	Retail Demand of Households in the Primary Trade Area.....	3-23
3-10	Household Retail Expenditures and Total Retail Sales, Primary Trade Area, 2010	3-25
3-11	Household Retail Expenditures and Total Retail Sales, Queens, 2010	3-25
3-12	Household Retail Expenditures and Total Retail Sales, New York City, 2010	3-25
3-13	2032 No Action Condition: Household Retail Expenditures and Total Retail Sales, Primary Trade Area.....	3-27
3-14	Proposed Project Retail Program By Development Phase	3-28
3-15	Estimated Retail Sales at Stores Introduced Under the RWCDS	3-29
3-16	Estimated Retail Demand from Households to Be Introduced by Proposed Project by 2032.....	3-29

3-17	Comparison of Estimated Retail Capture Rates in Primary Trade Area: Existing Conditions, Future Without the Proposed Project and Future With the Proposed Project in 2032	3-30
3-18	Population Change 2000 to 2010	3-32
3-19	Household Characteristics: 2000 and 2010	3-32
3-20	Income Characteristics and Trends	3-33
3-21	Housing Characteristics and Trends	3-34
3-22	Median Home Value and Contract Rent	3-34
3-23	Estimated Unprotected Rental Housing Units in the ¾-Mile Study Area	3-36
3-24	Estimated Population Potentially Vulnerable to Indirect Residential Displacement in the ¾-Mile Study Area	3-38
3-25	Population and Housing Growth 2032 Future Without the Proposed Project	3-39
3-26	Population and Housing Growth: 2032 Future With Proposed Project	3-40
3-27	Planned Destination Retail Projects Future Without the Proposed Project	3-48
3-28	Selected Supermarkets in Local Retail Concentrations	3-50
3-29	Selected Anchors in Regional Shopping Centers	3-52
4-1	Preliminary Screening Analysis Criteria	4-4
4-2	Public Schools Serving the Special Willets Point District, CSD 25 Sub-District 2 Enrollment and Capacity Data, 2010–2011 School Year	4-7
4-3	Projected Estimated Number of New Students Introduced By Development in the No Action Condition	4-8
4-4	Estimated Public School Enrollment, Capacity, and Utilization: No Action Condition (2018, 2028, and 2032)	4-9
4-5	Estimated Number of Students Introduced in Sub-District 2 of CSD 25: With Action Condition, 2018, 2028, 2032	4-10
4-6	Estimated Public School Enrollment, Capacity, and Utilization: With Action Condition, 2028	4-11
4-7	Estimated Public Elementary and Intermediate School Enrollment, Capacity, and Utilization: With Action Condition, 2032	4-12
4-8	Public Libraries Serving the Project Site	4-14
4-9	No Action Condition (2018, 2028, and 2032): Catchment Area Population	4-15
4-10	Phase 1B (2028) With Action Condition: Catchment Area Population	4-15
4-11	Phase 2 (2032) With Action Condition: Catchment Area Population	4-16
4-12	Publicly Funded Child Care Facilities Serving the Study Area	4-19
4-13	Hospitals and Emergency Rooms Within One Mile of Project Site	4-21
4-14	Outpatient Health Care Facilities Within the One-Mile Study Area	4-22

Willets Point Development

4-15	Police Protection Facilities.....	4-24
4-16	Fire Protection Facilities	4-26
5-1	2012 Population in the ¼-Mile Non-Residential Study Area.....	5-7
5-2	2010 Population in the ½-Mile Residential Study Area.....	5-7
5-3	Residential Population Age Distribution.....	5-8
5-4	Open Space Inventory	5-9
5-5	Existing Conditions: Adequacy of Open Space Resources	5-12
5-6	2018 No Action Condition: Residential Population Age Distribution	5-14
5-7	2018 No Action Condition: Adequacy of Open Space Resources	5-15
5-8	2028 No Action Condition: Adequacy of Open Space Resources	5-17
5-9	With Action Condition (2032): Residential Population Age Distribution	5-20
5-10	With Action Condition: Adequacy of Open Space Resources	5-21
5-11	With Action Condition: Open Space Ratios Summary	5-24
6-1	Incremental Shadow Durations	6-6
9-1	Essential Fish Habitat Designated Species for the Upper East River	9-8
11-1	Existing Water Demand	11-7
11-2	Existing Surface Coverage	11-11
11-3	2018 Projected Water Demand.....	11-14
11-4	2018 Proposed Surface Coverage.....	11-16
11-5	DEP Flow Volume Calculation Matrix: 2018 Existing and With Action Volume Comparison	11-17
11-6	2028 Projected Water Demand.....	11-19
11-7	2028 Proposed Surface Coverage.....	11-21
11-8	DEP Flow Volume Calculation Matrix: 2028 Existing and With Action Volume Comparison	11-21
11-9	2032 Projected Water Demand.....	11-23
11-10	2032 Proposed Surface Coverage.....	11-26
11-11	DEP Flow Volume Matrix: 2032 Existing and With-Action Volume Comparison...	11-27
12-1	Existing Solid Waste Generation in the Project Site	12-4
12-2	Solid Waste Generation of the RWCDs in 2032	12-6
13-1	Existing Annual Energy Consumption for the Project Site.....	13-4
13-2	Annual Energy Consumption for RWCDs, By Phase	13-7
14-1	Traffic Study Peak Hours—Without Mets Game	14-12

14-2	Traffic Study Peak Hours—With Mets Game	14-12
14-3	LOS Criteria for Signalized Intersections.....	14-13
14-4	LOS Criteria for Unsignalized Intersections.....	14-14
14-5	Existing Overall Intersection Level of Service Summary	14-15
14-6	Existing Traffic Lane Group Level of Service Summary	14-15
14-7	Hourly Parking Occupancy by Percentage of Spaces Occupied Per Facility Off-Street Parking Survey—Weekday Non-Game Day	14-24
14-8	Hourly Parking Occupancy by Percentage of Spaces Occupied Per Facility Off-Street Parking Survey—Saturday Non-Game Day	14-25
14-9	Hourly Parking Occupancy by Percentage of Spaces Occupied Per Facility Off-Street Parking Survey—Weekday Game Day	14-25
14-10	Hourly Parking Occupancy by Percentage of Spaces Occupied Per Facility Off-Street Parking Survey—Weekend Game Day	14-26
14-11	Existing Hourly On-Street Parking.....	14-29
14-12	No Action Projects in the Traffic Study Area.....	14-31
14-13	No Action Project Clusters	14-33
14-14	Vehicle Trips from Background Development Projects—Non-Game Day.....	14-34
14-15	Vehicle Trips from Background Development Projects—Game Day.....	14-34
14-16	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 1A (2018) No Action Conditions—Non-Game Day	14-36
14-17	Traffic Lane Group Level of Service Summary Comparison Existing Vs. Phase 1A (2018) No Action Conditions—Non-Game Day	14-36
14-18	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 1A (2018) No Action Conditions—Game Day	14-37
14-19	Traffic Lane Group Level of Service Summary Comparison Existing Vs. Phase 1A (2018) No Action Conditions—Game Day	14-37
14-20	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 1B (2018) No Action Conditions—Non-Game Day	14-39
14-21	Traffic Lane Group Level of Service Summary Comparison Existing Vs. Phase 1B (2018) No Action Conditions—Non-Game Day	14-39
14-22	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 1B (2018) No Action Conditions—Game Day	14-40
14-23	Traffic Lane Group Level of Service Summary Comparison Existing Vs. Phase 1B (2018) No Action Conditions—Game Day	14-40
14-24	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 2 (2032) No Action Conditions—Non-Game Day	14-42

Willets Point Development

14-25	Traffic Lane Group Level of Service Summary Comparison Existing Vs. Phase 2 (2032) No Action Conditions—Non-Game Day	14-42
14-26	Overall Intersection Level of Service Summary Comparison Existing Vs. Phase 2 (2032) No Action Conditions—Game Day	14-43

Foreword

This document is the Final Supplemental Environmental Impact Statement (FSEIS) for the Willets Point Development (the proposed project). The Draft Supplemental Environmental Impact Statement (DSEIS) for the proposed project was accepted as complete by the New York City Office of the Deputy Mayor's Office for Economic Development (ODMED) and a Notice of Completion for the DSEIS was issued on March 13, 2013. A public hearing was held on the DSEIS in conjunction with the City Planning Commission's public hearing pursuant to the Uniform Land Use Review Procedure (ULURP) on July 10, 2013, at the City Planning Commission, Spector Hall, 22 Reade Street, New York, NY, to accept oral and written comment on the DSEIS. The comment period was open for receiving written comments until July 22, 2013.

This FSEIS addresses all substantive comments made on the DSEIS during the public hearing and subsequent comment period. Those comments are summarized and responded to in Chapter 26, "Responses to Comments Received on the DSEIS." Written comments on the DSEIS are included in the FSEIS as Appendix F. Changes to the text and graphics from the DSEIS were made in this FSEIS, as necessary, in response to these comments.

Substantive changes between the DSEIS and FSEIS include:

- Revisions to Chapter 9, "Natural Resources," and Chapter 16, "Greenhouse Gas Emissions and Climate Change," to reflect the Federal Emergency Management Agency's new Best Available Flood Hazard Data and new projections on sea level rise from the New York City Panel on Climate Change.
- Revisions to Chapter 10, "Hazardous Materials," to reflect the Phase II Subsurface Investigation Work Plan and Health and Safety Plan for the Willets West portion of the project site that were approved by the New York City Department of Environmental Protection in July 2013.
- Revisions to Chapter 14, "Transportation" and Chapter 22, "Alternatives," to reflect further consultation with the New York City Department of Transportation regarding the feasibility of proposed mitigation measures. Revisions to Chapter 14 also reflect the commitment in the DSEIS to analyze three additional traffic and pedestrian analysis locations, as well as the analysis of another subway line.
- Revisions to Chapter 15, "Air Quality," to reflect the results of the refined mobile source analysis conducted for PM_{2.5} between the DSEIS and FSEIS in consultation with the New York City Department of Environmental Protection.
- Updated conclusions in Chapter 21, "Mitigation," in the areas of child care and transportation, and the effect of transportation mitigation measures on air quality and noise, to reflect further analysis of potential mitigation measures conducted between the DSEIS and FSEIS; and

Riverside Center FSEIS

- Chapter 26, “Responses to Comments Received on the DSEIS,” which is entirely new to the document.

All text changes since publication of the DSEIS are marked by double-underlining and strikeouts in this FSEIS. No double-underlining is used for the Foreword or Chapter 26, which are entirely new. *

A. INTRODUCTION

This Supplemental Environmental Impact Statement (SEIS) addresses proposed modifications to the previously approved Willets Point Development Plan for the approximately 61-acre Special Willets Point District in Queens, to include the proposed “Willets West” development on the surface parking lot west of the CitiField baseball stadium; the development of structured parking facilities on surface parking Lot D and South Lot along Roosevelt Avenue, adjacent to the stadium (see **Figure S-1**); and changes to the phasing of the project. With these modifications, the project site would comprise approximately 108.9 acres and the proposed project could result in up to 10.34 million square feet of development. This SEIS also considers changes in background conditions, including federal approval of the Freeway Access Modification Report (AMR) for new vehicular connections from the Special Willets Point District to the Van Wyck Expressway.

A Final Generic Environmental Impact Statement (FGEIS) for the Willets Point Development Plan (the Plan) was issued in September 2008 by the Office of the Deputy Mayor for Economic Development (ODMED) as lead agency under the New York State Environmental Quality Review Act (SEQRA), its implementing regulations (6 NYCRR Part 617), and New York City Environmental Quality Review (CEQR). The approved project was for redevelopment of a largely underutilized site with substandard conditions and environmental degradation into a lively, sustainable community and regional destination with approximately 8.94 million square feet of residential, retail, hotel, convention center, entertainment, commercial office, community facility, open space, and parking uses.

The proposed modifications to the previously approved Willets Point Development Plan require public review, including by the local Community Board and the Queens Borough President, and approvals by government agencies, including the Office of the Deputy Mayor for Economic Development, the New York City Planning Commission (CPC), and the City Council. Because it has been determined that the proposed project may result in new or greater significant adverse impacts than were disclosed in the 2008 FGEIS, the proposed project requires review and the preparation of an SEIS under CEQR.

B. PROJECT BACKGROUND

Since World War II, there have been numerous attempts to redevelop Willets Point, which became known over the years for its many auto repair businesses and junkyards. Since 2000, these planning efforts have accelerated. In 2001, the City’s Department of Housing Preservation and Development (HPD) design workshop explored potential redevelopment ideas and recommended land uses that would connect Willets Point with neighboring communities and complement nearby attractions and facilities. In 2002, the City created the Downtown Flushing Task Force, which outlined land use and economic goals for the redevelopment of Willets Point in its Downtown Flushing Development Framework. The Downtown Flushing Development

Willets Point Development

Framework became the starting point for the City's creation of the Willets Point Development Plan. The numerous actions required for the Plan—which included the creation of a new special zoning district (the Special Willets Point District) and an urban renewal plan for the area—required review under SEQRA and CEQR.

An FGEIS for the Willets Point Development Plan was issued in September 2008 by ODMED as lead agency under SEQRA, its implementing regulations (6 NYCRR Part 617), and CEQR. The Willets Point Development Plan was approved by the City Council in 2008. Subsequent technical memoranda assessed the potential effects of modifications to the proposed actions and were accepted by ODMED; SEQRA findings were issued on February 11, 2011.

In May 2011, the City issued a revised Request for Qualifications and Request for Proposals for the redevelopment of this area. The City has also undertaken several measures that support the goals of the Plan, including measures related to site acquisition, assistance for District workers, advancement of the proposed connections to the Van Wyck Expressway, and ongoing infrastructure work. In December 2011, the City also broke ground on the new sanitary and storm water mains that will provide new public sanitary sewer service to support the redevelopment of the District and adjacent areas and replace an inadequately sized storm water sewer and outfall to help alleviate chronic flooding that occurs in the District and adjacent areas. Adjacent to the Special Willets Point District, the new CitiField stadium opened in 2009, replacing the former Shea Stadium, and the area formerly occupied by Shea Stadium was converted to a surface parking lot.

In 2012, in response to a competitive Request for Proposal process, the Queens Development Group, LLC (QDG)—a joint venture between the Related Companies and Sterling Equities—was selected as the City's designated developer for Phases 1A and 1B of the Willets Point Development Plan.¹ QDG is proposing to include in its proposed development additional land beyond the boundaries of the Special Willets Point District in order to develop portions of the main CitiField stadium parking field ("Willets West") and CitiField parking fields south of Roosevelt Avenue. QDG is also proposing to develop interim parking uses on a portion of the land within the Special Willets Point District to accommodate the stadium's parking demand during the initial phase of the area's proposed redevelopment. The discretionary actions needed for the proposed modifications include a zoning text amendment, a special permit to allow surface parking and recreational uses within the Special Willets Point District, and modification of the City's existing lease for the CitiField parking lot, as well as potential additional actions discussed below.

PRIOR ENVIRONMENTAL REVIEW

The 2008 FGEIS examined the potential for significant impacts resulting from the redevelopment of the project site in the impact categories of land use, zoning, and public policy; socioeconomic conditions; community facilities; open space; shadows; historic resources; urban design and visual resources; neighborhood character; natural resources; hazardous materials; waterfront revitalization program; infrastructure; solid waste and sanitation; energy; traffic and parking; transit and pedestrians; air quality; noise; construction impacts; and public health. The 2008 FGEIS found that no significant adverse environmental impacts would result from the proposed development Plan with respect to land use, zoning, and public policy; socioeconomic

¹ Formerly Phase 1 in Technical Memorandum #4, with some adjustments to footprint.

conditions; open space; shadows; urban design and visual resources; neighborhood character; natural resources; waterfront revitalization program; infrastructure; solid waste and sanitation; energy air quality; construction impacts; and public health. Potentially significant impacts were identified for publicly funded child care, historic resources, hazardous materials, traffic, transit and pedestrians, and noise.

Subsequent to the issuance of the 2008 FGEIS, CPC proposed several modifications to the Special Willets Point District zoning regulations. These modifications were described, and their potential for significant adverse environmental impacts examined, in a technical memorandum dated September 23, 2008 (Technical Memorandum #1), which found that there were no additional impacts due to the modifications that had not been disclosed in the 2008 FGEIS. CPC voted in favor of the Willets Point Development Plan with those modifications on September 24, 2008.

Following the CPC vote, new information became available related to: negotiated property acquisition by the City in the District; Phase II Environmental Site Investigations (ESIs) in the District; the amount of affordable housing to be provided in the District (an increase from 20 to 35 percent); and projected school and day care populations. This information was described, and its potential to result in significant adverse environmental impacts not previously identified was examined, in a technical memorandum dated November 12, 2008 (Technical Memorandum #2). That technical memorandum concluded that none of the newly available information would lead to significant adverse environmental impacts that had not been identified and addressed in the 2008 FGEIS. The City Council voted to approve the Willets Point Development Plan with the CPC modifications on November 13, 2008.

In 2009, the City considered the effect of the economic downturn on the Willets Point project. The City anticipated that economic conditions would make it challenging for developers to finance the acquisition and remediation of the entire Willets Point site at one time and prior to any development, as described in the 2008 FGEIS. In a technical memorandum dated November 23, 2009 (Technical Memorandum #3), an Adjusted Plan for Willets Point was analyzed similar to the Staged Acquisition Alternative analyzed in the FGEIS. In the Adjusted Plan, remediation and development of an initial portion of the District would have proceeded first, followed by remediation and development of the remaining portion of the District. The Adjusted Plan assumed the same overall development program at full build-out as the Staged Acquisition Alternative (with revisions described in the prior technical memoranda), but anticipated a smaller development footprint during the first years of development, with approximately 70 percent as much floor area in the initial phase compared with the Staged Acquisition Alternative.

In a technical memorandum dated February 10, 2011 (Technical Memorandum #4), the City considered an Updated Plan that was similar to the Adjusted Plan analyzed in the 2009 technical memorandum as well as to the Staged Acquisition Alternative analyzed in the 2008 FGEIS. Compared with both the Adjusted Plan and the Staged Acquisition Alternative, the Updated Plan anticipated a smaller development footprint and less overall development (approximately 1.345 million gross square feet or gsf) in the first phase; however, at full build-out the Updated Plan would have developed the District with the same gross floor area and mix of uses as the Approved Plan (with subsequent revisions described in the prior technical memoranda) and would have had the same controls on floor area ratios set forth in the provisions of the Special District zoning text that had been approved by CPC and the City Council.

A substantial difference between the Approved Plan and the Updated Plan was the timing of property acquisition and construction phasing. Under the Approved Plan, the necessary

remediation, grading, and infrastructure improvements would have taken place across the District at the beginning stages of construction; in comparison, with the Updated Plan (as with the Staged Acquisition Alternative and the Adjusted Plan), development activities would have proceeded incrementally, with the necessary remediation, grading, infrastructure improvements, and construction activities associated with the buildings in the southwestern portion of the District occurring first, and construction activities on the remainder of the District following. Whereas the Staged Acquisition Alternative and Adjusted Plan assumed the District's connections to the Van Wyck Expressway would be constructed before the end of the first phase of development, with the Updated Plan these connections would have been completed no later than after the end of the first phase of development and before the first building to be developed in the second phase of construction is completed. Some negotiated acquisition might also have occurred within the remainder of the District during the initial phase of development.

In March 2012, the New York State Department of Environmental Coordination (NYSDEC) approved a State Pollutant Discharge Elimination System (SPDES) Construction Dewatering and Discharge Permit for construction of the proposed new sanitary and storm water mains for the Willets Point area. As described above, these improvements are currently being constructed.

The new connection to the Van Wyck Expressway, which was assumed in the 2008 FGEIS and subsequent technical memoranda, was subject to federal approval of the Freeway AMR. A Finding of No Significant Impact was issued and the AMR was approved in April 2012; the City has committed to provide capital funds for its construction.

C. PROJECT DESCRIPTION

SITE DESCRIPTION

The project site is composed of three discrete areas roughly bounded by Shea Road and Northern Boulevard to the north, the Van Wyck Expressway to the east, Roosevelt Avenue and the Metropolitan Transportation Authority (MTA) Corona Rail Yard to the south, and Shea Road to the west (see **Figures S-1** and **S-2**). The “Willets Point” portion of the project site (the Special Willets Point District) comprises approximately 61 acres, approximately 15.8 acres of which are within public street rights-of-way, approximately 0.6 acres of which are owned by the MTA, and the remainder of which is a mix of privately owned land and land owned by the City. The Willets Point area comprises 128 tax lots and one partial lot (Block 1833, Lot 1) located on 14 blocks. Since the FGEIS was completed in 2008, the City has acquired, or is in contract to purchase, 95 percent of the land area within the proposed Phase 1A/1B footprint (Assemblage Option 2) in the District, and has control of 4 lots in the remainder of the District.

The “Willets West” portion of the project site is mapped parkland that comprises an approximately 30.7-acre section of the surface parking field west of CitiField. This area comprises a portion of Block 1787, Lot 20. The “Roosevelt Avenue” portions of the project site comprise three CitiField-related surface parking lots (South Lot and Lots B and D) along Roosevelt Avenue south and southwest of CitiField. The Lot B parking lot, which comprises a portion of Block 1787, Lot 20, is approximately 4.7 acres in size; the South Lot and Lot D parking lot, which comprise a portion of Block 2018, Lot 1500, are together approximately 12.1 acres in size. Lot D and South Lot are used for commuter parking and United States Tennis Association (USTA) National Tennis Center (NTC) events when baseball games are not in progress.

In total, the project site comprises approximately 108.9 acres.

GOALS AND OBJECTIVES

The proposed project is intended to remediate and transform the area surrounding CitiField, which is largely separated from adjoining neighborhoods by major highways, into a thriving new neighborhood and regional destination. The project would expand on the goals and objectives of the original (2008) Willets Point Development Plan. By providing development that spans both sides of the new CitiField, the proposed project would allow for a more comprehensive and continuous neighborhood linking Flushing and Corona. The environmental degradation of the Special Willets Point District would be remediated. The commercial components of the proposed project would provide jobs and create new retail, hotel and entertainment uses that would complement the adjacent sports venue and strengthen economic activity in the neighborhood, borough, and City. The substantial residential component (which includes affordable housing units) would accommodate a portion of the City's current and future housing needs. The new structures and open spaces are intended to create an active streetscape that includes retail uses as part of a diverse mixed-use program, enhancing the pedestrian experience.

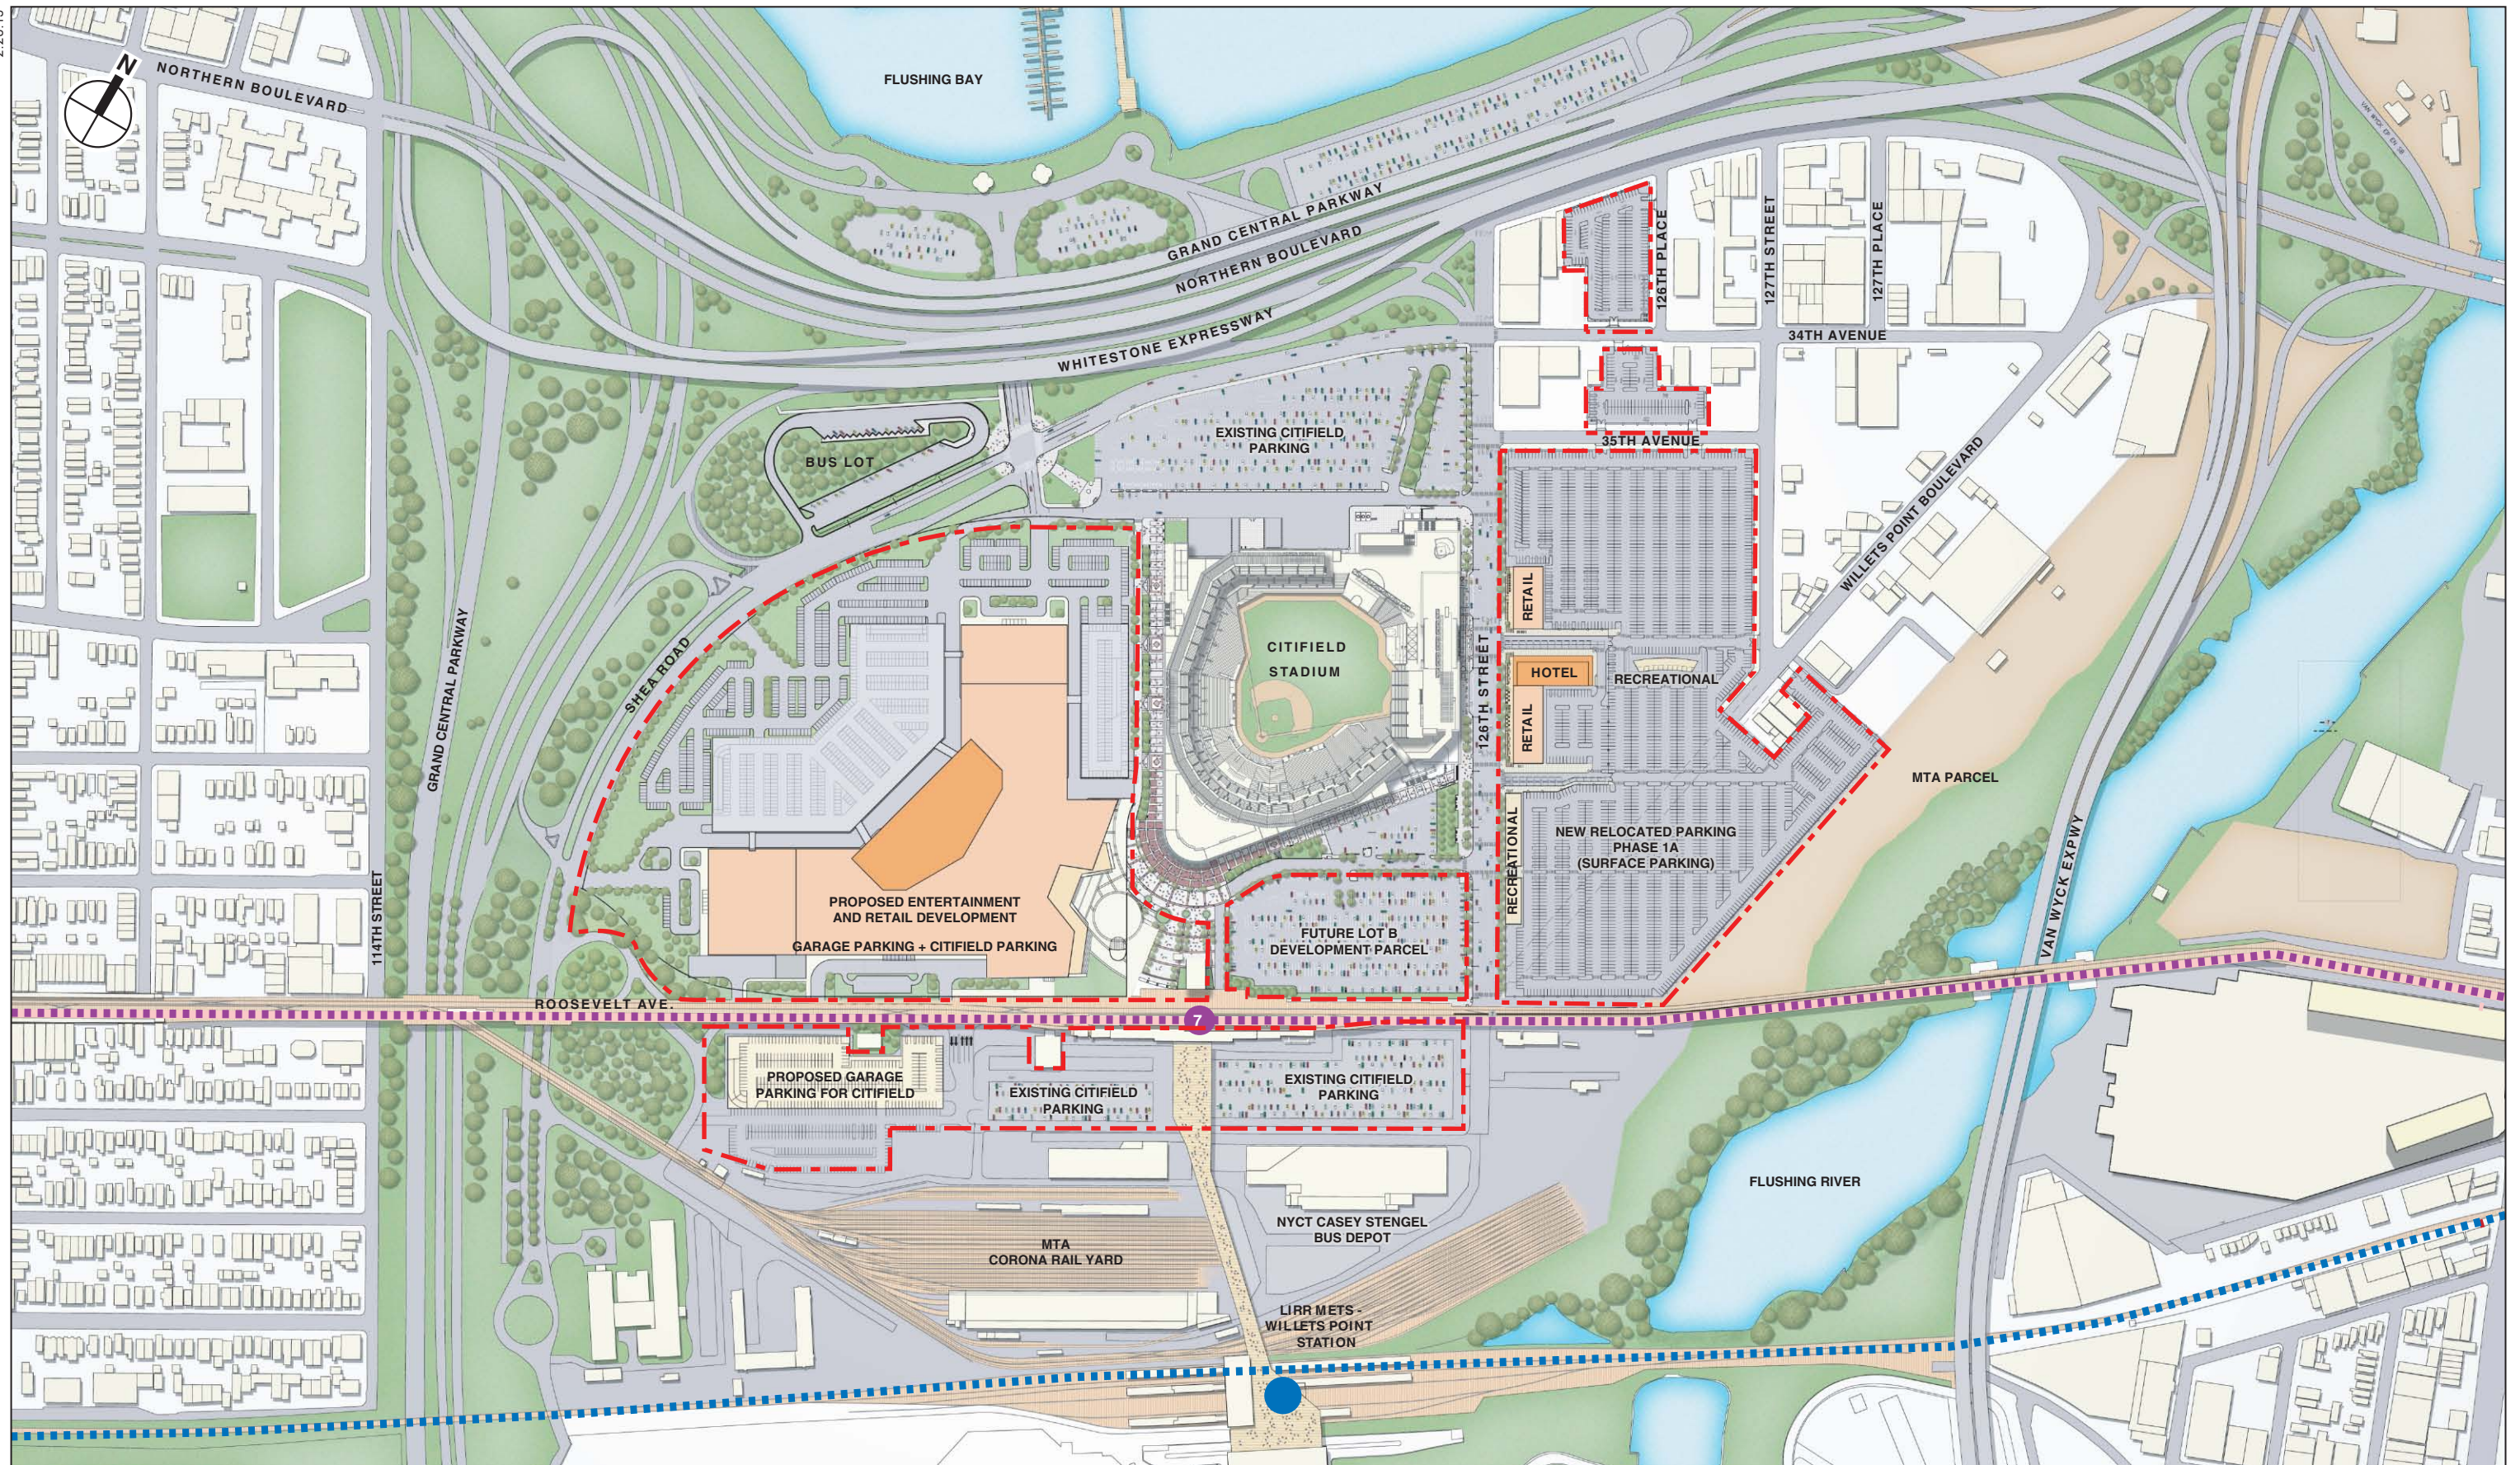

PROPOSED PROJECT

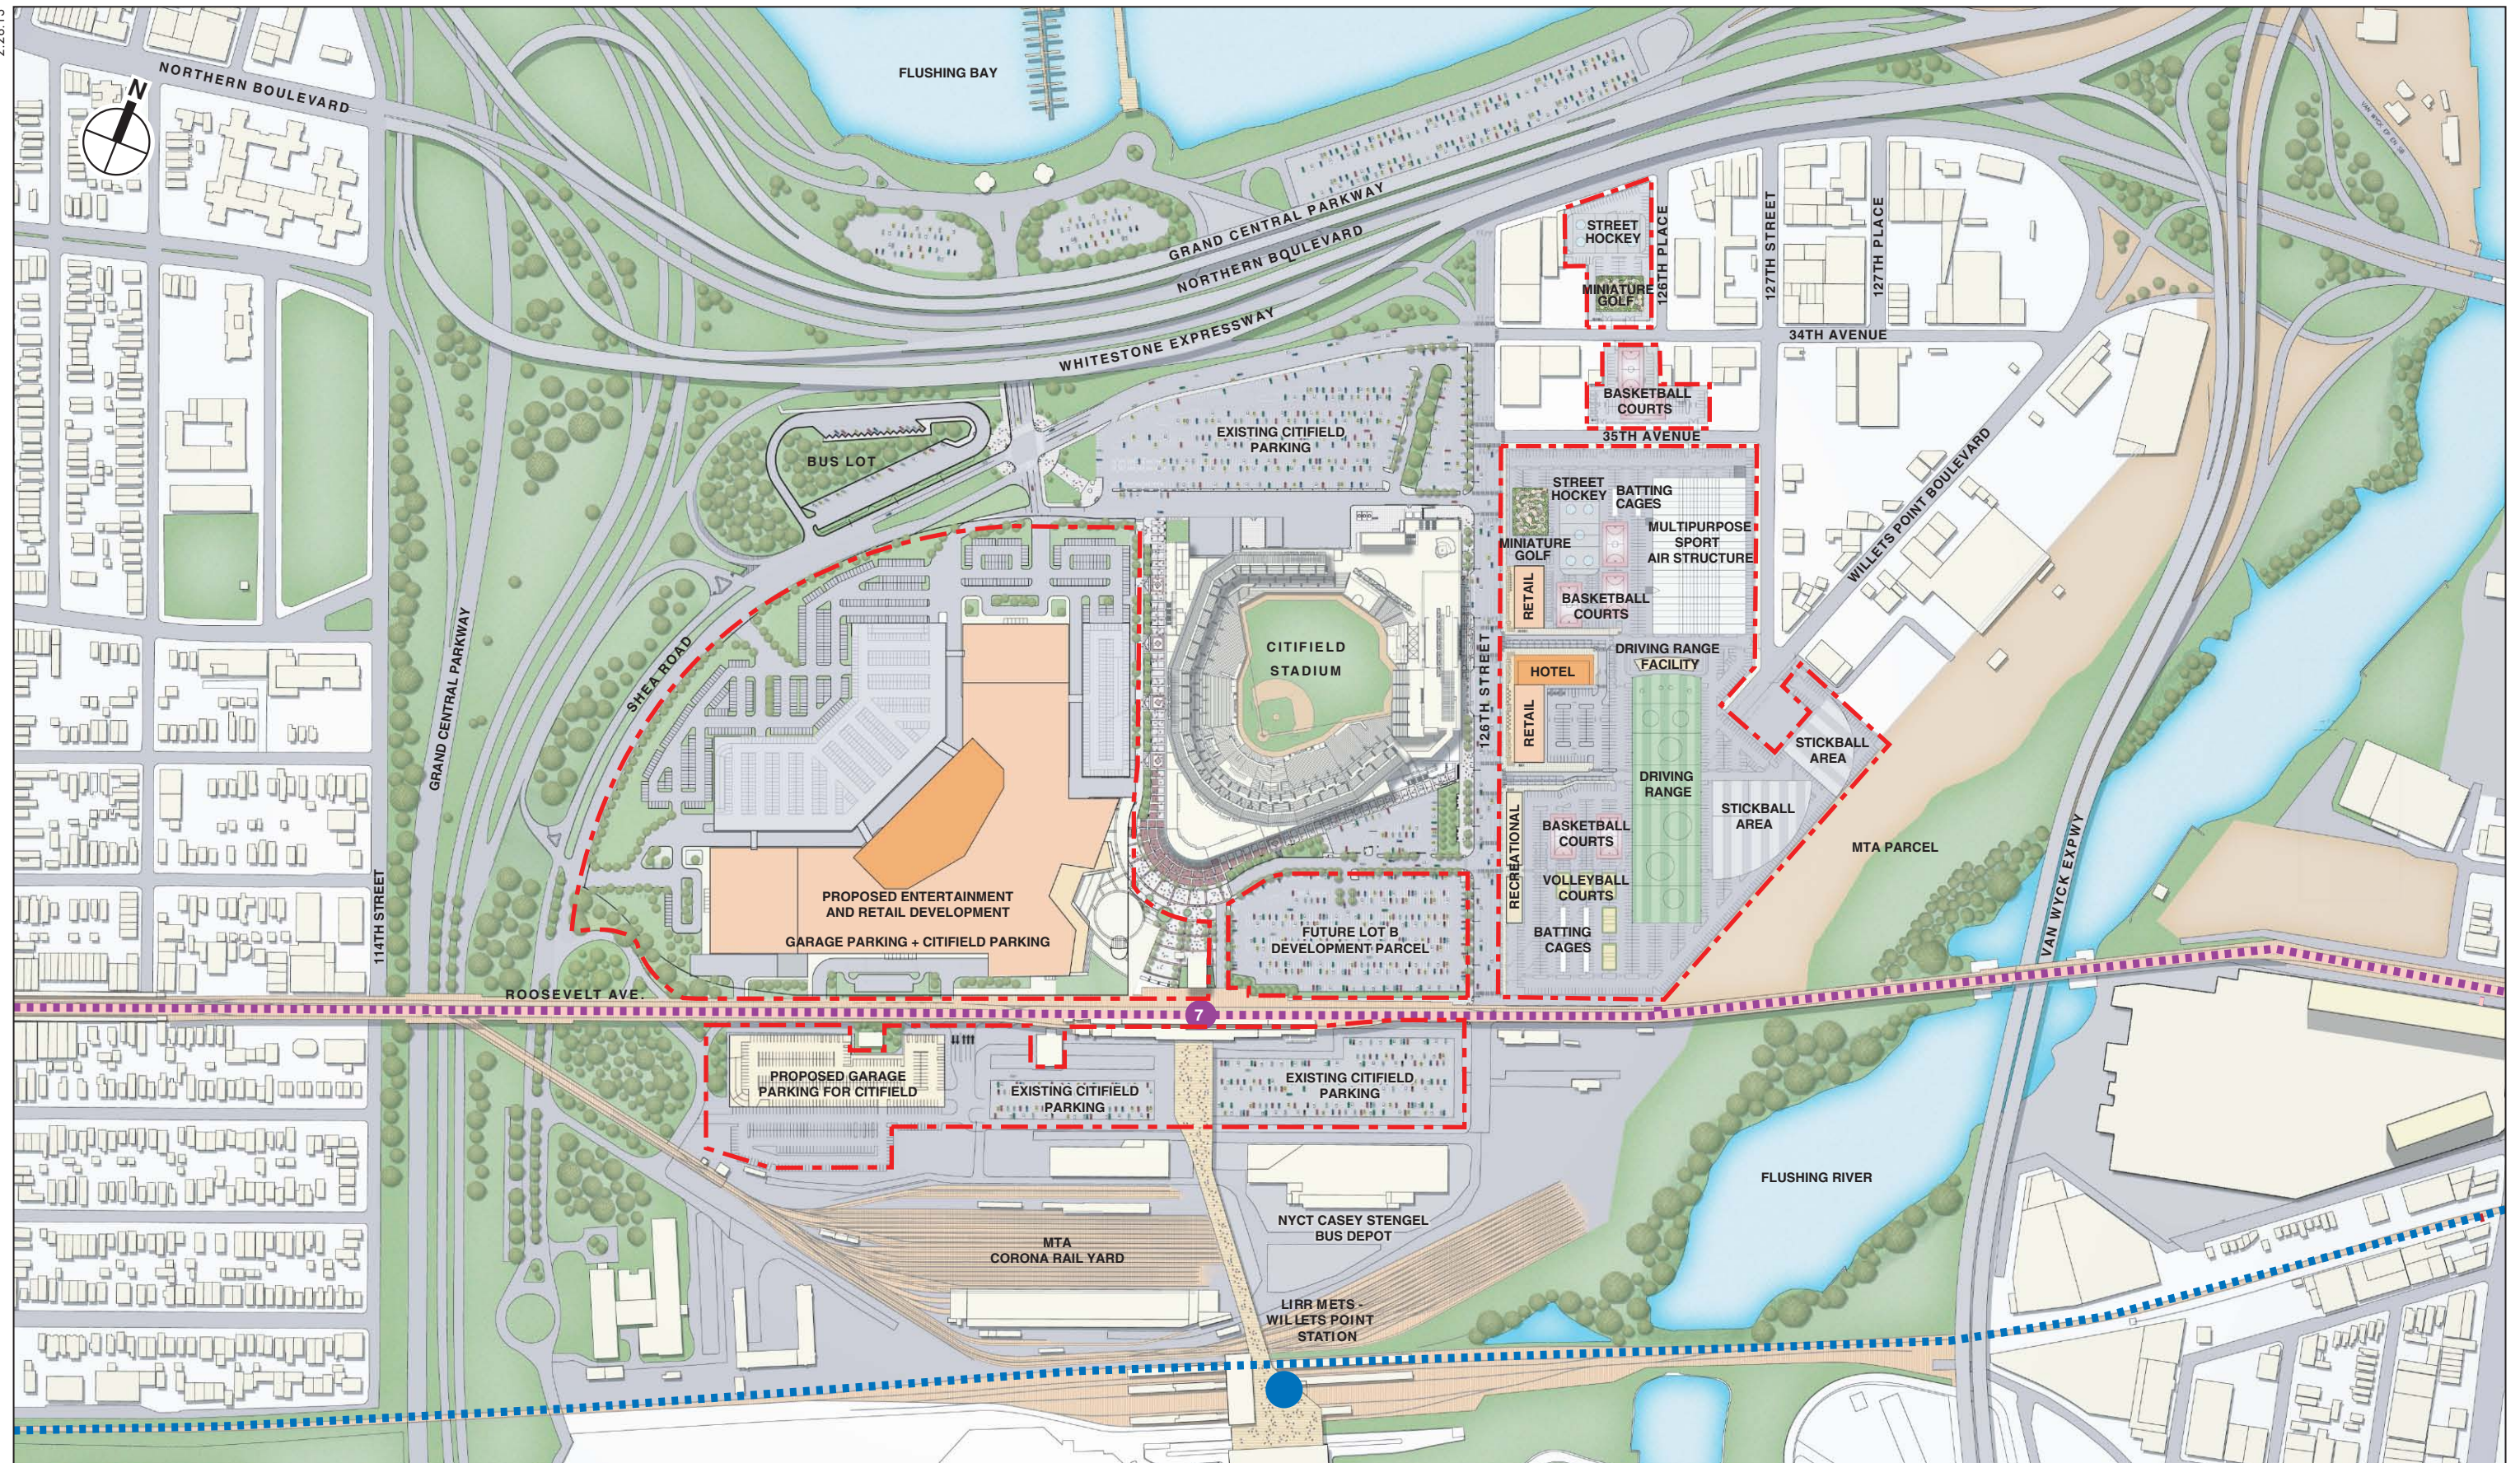

The proposed project would redevelop the Willets Point/CitiField area with a mix of uses that is expected to be completed by 2032. The redevelopment would incorporate a development in the Special Willets Point District substantially as anticipated and analyzed in the 2008 FGEIS and subsequent technical memoranda, as well as a major entertainment/retail component and parking adjacent to CitiField. Changes to the development analyzed here versus that analyzed in the 2008 FGEIS include an increase in the overall amount of retail development from 1.7 million square feet to 2.65 million square feet. This increase results from the 1.4 million gross square feet (1 million leasable square feet) of development at Willets West combined with a concurrent reduction in the overall amount of retail in the Special Willets Point District from 1.7 million square feet to 1.25 million square feet. The DSEIS also assumes 5.85 million gross square feet of residential development to match the highest amount of residential development analyzed in the 2008 FGEIS (in the No Convention Center Scenario), and a 230,000-square-foot school rather than the 2008 FGEIS's 130,000-square-foot school to accommodate a greater amount of the project's potential school seat demand.

The project is anticipated to proceed in three continuous phases, as follows.

PHASE 1A

The first phase of the project would commence with the remediation and development of an approximately 23-acre portion of the Special Willets Point District and the development of "Willets West" on the existing parking lot west of CitiField (see **Figures S-3a** and **S-3b**). The 23-acre portion of the District would be remediated to address any hazardous materials issues. Upon completion of the environmental remediation, a 200-room hotel and associated parking, and approximately 30,000 square feet of retail space would be constructed above the floodplain along the east side of 126th Street, activating the 126th Street corridor—according to the District's regulations—with a 20-foot-wide public esplanade. A 2,750-space surface parking area would be developed east of the retail and hotel uses. The parking area would be converted to active recreational use a minimum of 6 months per year. This interim parking/recreational area would be replaced by permanent development in Phase 1B, as described below.

Willets Point Development

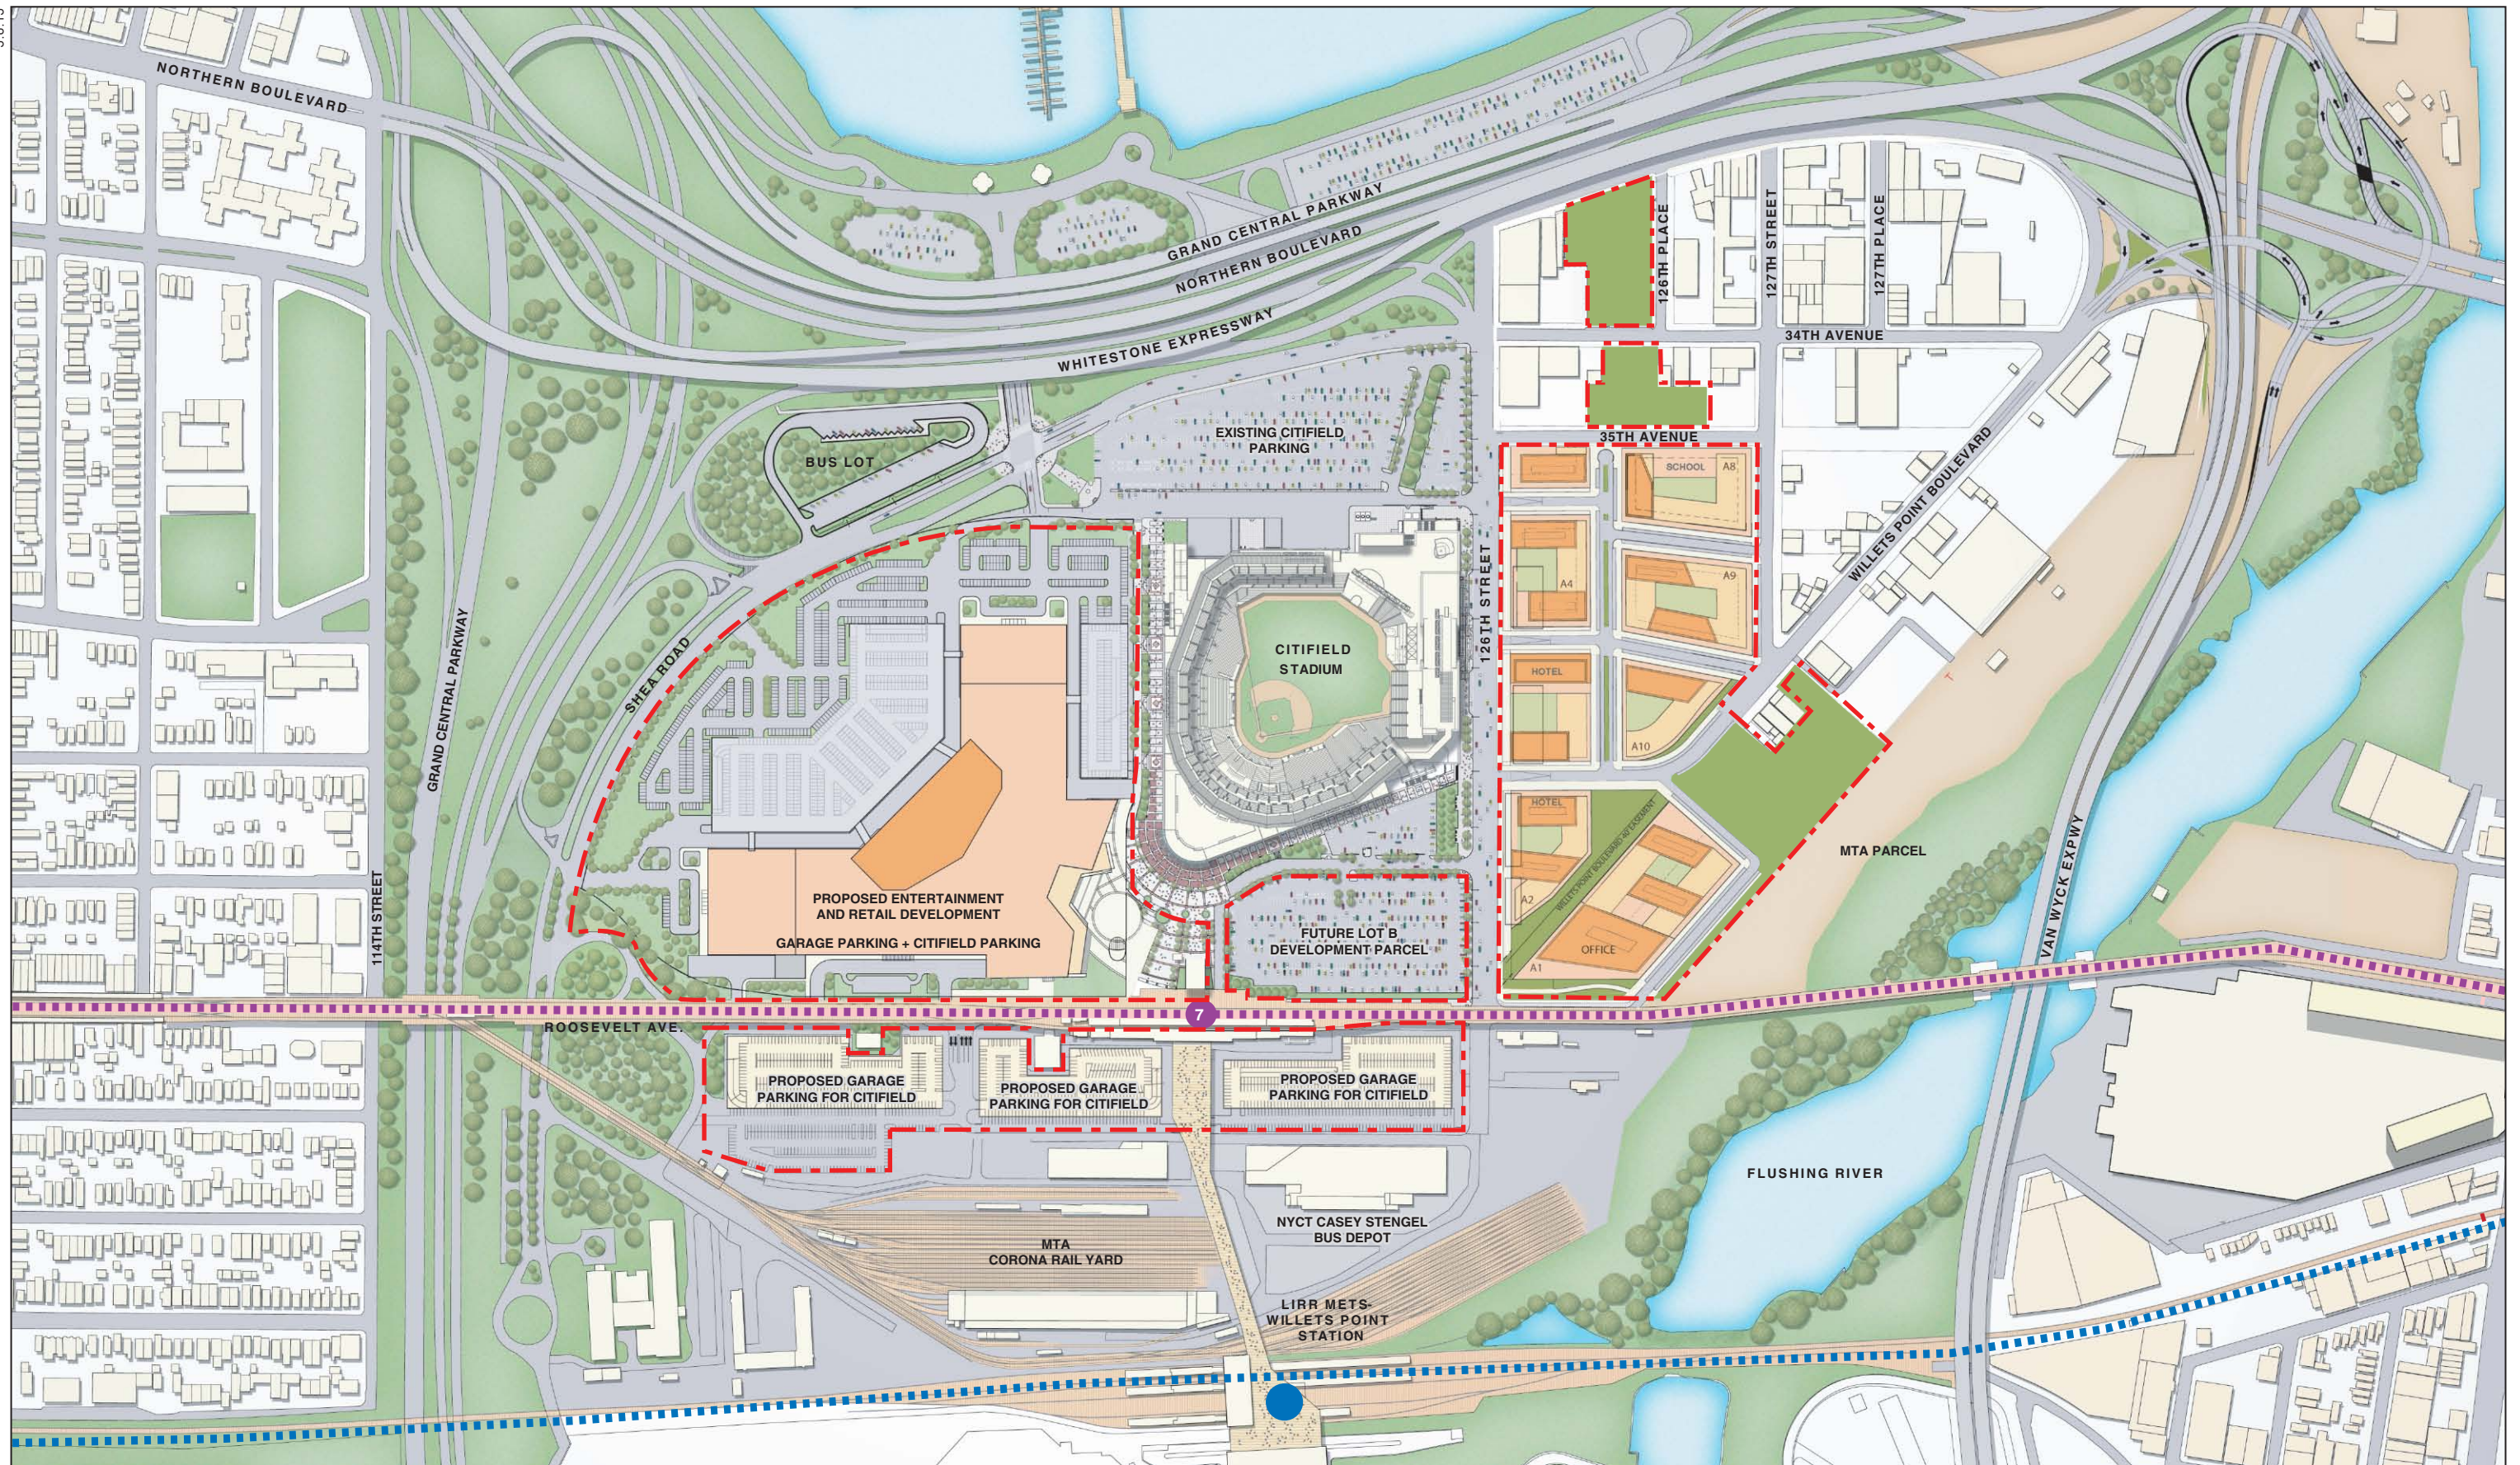

In tandem with the development of the parking area, “Willets West”—an entertainment and retail center of approximately 1.4 million gross square feet (approximately one million square feet of gross leasable area)—would be developed on a portion of the surface parking lot west of CitiField. This entertainment and retail center, which would be developed on mapped parkland as authorized by statute, would allow for more comprehensive transit-oriented development around the Mets/Willets Point stops on the No. 7 train and Long Island Rail Road and would support the economic development of the area. The complex could include over 200 retail stores, including anchor and “mini” anchor retailers, as well as movie theaters, restaurant and food hall spaces, and entertainment venues. Surface parking and a parking structure also would be developed in this location, including 2,500 new spaces for the entertainment/retail center and 400 spaces of replacement parking for use by the Mets. It is anticipated that the Willets West development, by building a critical mass of uses, would create a new destination that would serve as a catalyst for the subsequent build-out of the Willets Point area. In addition, the westernmost CitiField surface parking lot south of Roosevelt Avenue (a portion of the South Lot) would be redeveloped as a structured parking facility, to replace a portion of the CitiField parking spaces formerly located on the Willets West site. Phase 1A is expected to be completed in 2018.

PHASE 1B

In the next phase of the project, the interim surface parking lot/recreational space created during Phase 1A within the Special Willets Point District would be developed, transforming this formerly contaminated area into a new neighborhood. Consistent with the goals and objectives of the Willets Point Development Plan, Phase 1B of the proposed project would create more development on the east side of 126th Street, featuring a more active, attractive streetscape, providing new jobs, and complementing the adjacent CitiField. In addition, the new development would complement the new Willets West development created in Phase 1A. The residential units to be developed in this phase (which include affordable housing units) would accommodate a portion of the City’s current and future housing needs, and the proposed school would address the project-generated school seat demand.

The program for this development would include approximately 4.23 million square feet (sf) of development: 2.49 million sf of residential use (2,490 units, 872 of which would be affordable), 875,000 sf of retail use, 500,000 sf of office use, approximately 235,000 sf of hotel use (290 rooms), 25,000 sf of community facility use, and a 105,000 sf public school, along with parking and more than six acres of new public open space (see **Figures S-4** and **S-5**). This development is anticipated to be developed block by block, substantially as envisioned in the Willets Point Development Plan. In addition, new structured parking facilities would be constructed on portions of the CitiField leasehold along Roosevelt Avenue (South Lot and Lot D) to replace the 2,750 CitiField parking spaces formerly located within the Special Willets Point District. The 75 accessory parking spaces created in Phase 1A for the hotel would remain in the District.

Construction of the new Van Wyck Expressway access ramps—which was anticipated in the 2008 FGEIS and for which the City has received approval from the Federal Highway Administration—is slated to be completed in 2024. Construction of the Phase 1B program is anticipated to take four years; however, the buildings within the District are not expected to be occupied until after the ramp improvements have been completed. The ramps would be operational prior to the occupancy of the Phase 1B buildings. Phase 1B is expected to be completed in 2028.

Publicly-Accessible Open Space within the Special Willets Point District

Private Open Spaces within the Special Willets Point District

Existing Conditions

Illustrative rendering of Phase 1A

Illustrative rendering of Phase 1B

PHASE 2

In Phase 2, the remainder of the Special Willets Point District would be built out substantially as described in the 2008 FGEIS. Upon completion of Phase 2, the full build-out of all phases of the District is anticipated to total approximately 8.94 million square feet of development, including: up to 5.85 million sf of residential use (approximately 5,850 units, of which 2,048 would be affordable); up to 1.25 million sf of retail; approximately 500,000 sf of office; up to 400,000 sf of convention center use; up to 560,000 sf of hotel use (approximately 700 rooms); up to 150,000 sf of community facility use; approximately 230,000 sf of public school use; and a minimum of 8 acres of publicly-accessible open space. The number of proposed parking spaces within the District would be determined based on project-generated demand, but is anticipated to be no more than the 6,700 spaces identified in the 2008 FGEIS. Remediation of the portions of the District not already developed in Phases 1A and 1B is assumed to be completed prior to 2028. As with Phase 1B, Phase 2 is anticipated to be completed incrementally over four years, with full build-out expected to be completed by 2032. A developer for Phase 2 has not yet been selected. Phase 2, illustrated in **Figure S-6**, assumes a similar generic program to that analyzed in the 2008 FGEIS, while Phase 1A and Phase 1B have discrete programs and designs.

Table S-1 below provides a summary of the proposed program, by phase, with a summary of the proposed new parking and relocation of existing CitiField parking shown in **Table S-2**.

Table S-1
Summary of Proposed Program, by Phase

Use (sf)	Project Area	Phase 1A	Phase 1B	Phase 2	Totals by Use
Retail	SWPD	30,000	875,000	345,000	1,250,000
	WW	1,400,000 ¹			1,400,000
Hotel	SWPD	160,000 [200 rooms]	235,000 [290 rooms]	165,000 [210 rooms]	560,000 [700 rooms]
Residential	SWPD		2,490,000 [2,490 units]	3,360,000 [3,360 units]	5,850,000 [5,850 units]
School	SWPD		105,000	125,000	230,000
Community Facility	SWPD		25,000	125,000	150,000
Office	SWPD		500,000		500,000
Convention Center	SWPD			400,000	400,000
Open Space	SWPD	TBD	6 acres	5 acres	8 acres ²
Total		1,590,000 gsf	4,230,000 gsf 6 acres	4,520,000 gsf 5 acres	10,340,000 gsf 8 acres
Notes: SWPD = Special Willets Point District WW = Willets West ¹ Anticipated to include cinema use and approximately 400,000 sf of common area and back of house space. ² Some of the open spaces developed in Phase 1B would be replaced or expanded with new open space in Phase 2. The cumulative total of open space to be developed within the District is 8 acres.					

Publicly-Accessible Open Space within the Special Willets Point District

Private Open Spaces within the Special Willets Point District

Table S-2

Proposed New and Replacement Parking Spaces (Cumulative by Phase)

Project Area	Existing Conditions			Phase 1A			Phase 1B			Phase 2		
	CitiField	New	Total	CitiField	New	Total	CitiField	New	Total	CitiField	New	Total
WW	4,100	-	4,100	400	2,500	2,900	400	2,500	2,900	400	2,500	2,900
SWPD	-	-	-	2,750	75	2,825	-	2,700	2,700*	-	6,700	6,700*
South Lot/Lot D	1,795	-	1,795	2,745	-	2,745	5,495	-	5,495	5,495	-	5,495
Total	5,895	-	5,895	5,895	2,575	8,470	5,895	5,200	11,095	5,895	9,200	15,095

Notes: SWPD = Special Willets Point District
 WW = Willets West
 "CitiField" parking is the total number of spaces within the project site that either currently or would in the future serve events at CitiField. Existing Willets West spaces lost to development would be replaced as shown, in Phases 1A and 1B.
 "New" parking is the total number of parking spaces that would serve the proposed project.
 *These reflect newly developed spaces for Phase 1A, Phase 1B and Phase 2 (2,750 Mets spaces would be relocated to South Lot/Lot D in Phase 1B).

COMPARISON OF SEIS AND FGEIS

The actions requested to facilitate the proposed project would not change the maximum overall development of 8.94 million square feet permitted within the District. However, the proposed project would differ from the development analyzed in the 2008 FGEIS in that the FGEIS program did not include any development outside of the District and did not anticipate the use of the District for surface public parking and recreation. Accordingly, the DSEIS will analyze 1.4 million gross square feet (1 million leasable square feet) of retail that would be developed at Willets West, the interim parking and recreational uses that would occur within the District, and the proposed parking garages at Willets West, the South Lot and Lot D. Given the retail development that would occur in Willets West, it is assumed that less destination retail would be developed within the District, so this SEIS analyzes 1.25 million square feet of retail within the District rather than 1.7 million square feet. Although the residential program and its projected population have not changed since the 2008 FGEIS (as analyzed in the No Convention Center Scenario), an increase of 100,000 square feet of school space is assumed in this DSEIS to reflect updated projections of increased school seat demand citywide and in Queens in particular. See **Table S-3** below for a comparison of the proposed project for the District vs. the program analyzed in the 2008 FGEIS. Uses not noted below are not proposed to change from the program analyzed in the 2008 FGEIS.

Table S-3

**Totals by Use in Special Willets Point District
Proposed Program vs. 2008 FGEIS**

Use	FGEIS (gsf)	Proposed Program (gsf)
Retail	1,700,000	1,250,000
Residential	5,550,000 [5,500 units] (Convention Center Scenario) 5,850,000 [5,850 units] (No Convention Center Scenario)	5,850,000 [5,850 units]
Public School	130,000	230,000

The 2008 FGEIS analyzed a Staged Acquisition Alternative, in which the western portion of the District was assumed to be developed by 2013 and the remaining portion of the District would be built out by 2017. Technical Memoranda #3 and #4 also considered the phasing of development in the District over two analysis years. In comparison, this SEIS analyzes the development of the proposed project over three analysis years (2018, 2028, and 2032).

PURPOSE AND NEED

As described above, the proposed project would remediate and transform the area surrounding CitiField. The proposed entertainment and retail destination of Willets West would complement the anticipated development within the District, and both would connect Flushing to the east with Corona to the west through the creation of a more continuous series of uses along Roosevelt Avenue stretching from east of the Flushing River to west of the Grand Central Parkway. Over 2,000 units of affordable housing would be developed to accommodate a portion of the City's current and future affordable housing needs. The project's retail components would capture spending that currently is lost to the surrounding suburbs, and would thereby strengthen economic activity in the neighborhood, borough, and City. The proposed project would represent a significant investment by the City to improve the infrastructure of the project area. Raising the District portion of the project site out of the floodplain would not only minimize the potential loss of life, structures, and natural resources caused by flooding and erosion, but would also protect the City's new infrastructure investment. Eliminating flooding within the District and improving the quality of the soil substrate on the site would also improve water quality in Flushing Bay.

DISCRETIONARY ACTIONS SUBJECT TO CEQR AND SEQRA

The proposed project would require multiple City and State approvals. These anticipated approvals may include:

- Zoning text amendment to ZR Section 124-60 to allow use modifications as part of a phased development within the Special Willets Point District;
- Special permit pursuant to ZR Section 124-60 to allow surface parking/open and enclosed privately operated recreation uses for Phase 1A within the Special Willets Point District;
- Modification of the existing lease for the CitiField property and adjacent parking properties;
- Mayoral and Queens Borough Board approval of the business terms pursuant to New York City Charter Section 384(b)(4);
- Approval by the New York City Industrial Development Agency (IDA) or other government agencies for the waiver of mortgage recording tax for property within the Special Willets Point District; and
- Minor modification of the previously approved changes to the City Map to modify the staging for the closure of City Streets. This modification would not result in the demapping of any additional City streets beyond those previously approved for demapping.

In addition to the discretionary approvals listed above, Public Design Commission approval also would be required for the Willets West development. Confirmation that all proposed buildings fall within the maximum Federal Aviation Administration (FAA) height limitations also would be sought from the FAA; however, no approval or permit to exceed such permitted heights is anticipated to be sought.

D. ANALYTICAL FRAMEWORK FOR ENVIRONMENTAL REVIEW

OVERVIEW

The SEIS for the development of the project site supplements the 2008 FGEIS. The SEIS will contain:

- A description of the proposed project and its environmental setting;
- A description of the evolution of project site conditions since 2008;
- The identification and analysis of any significant adverse environmental impacts of the proposed project, including the short- and long-term impacts;
- The identification of any significant adverse environmental impacts that cannot be avoided if the proposed project is implemented;
- A discussion of reasonable alternatives to the proposed project;
- The identification of irreversible and irretrievable commitments of resources that would be involved in the proposed project, should it be implemented; and
- The identification and analysis of practicable mitigation to address any significant adverse impacts generated by the proposed project not previously identified in the FGEIS.

ANALYSIS APPROACH

Each chapter of the SEIS first summarizes the conclusions of the 2008 FGEIS and subsequent technical memoranda for that particular technical area. Then, the chapter assesses whether changes in the analysis years and background conditions, variations between the proposed project and the redevelopment assumed in the 2008 FGEIS, and new proposed actions could result in new or different significant adverse impacts than those disclosed in the 2008 FGEIS. Existing conditions are updated as necessary and presented. Next, the chapter projects changed existing conditions forward into the future without the proposed project, incorporating the most recent information available on known land-use proposals and, as appropriate, changes in anticipated overall growth. Finally, the future with the proposed project is described, the differences between the future without and with the proposed project are measured, and any significant adverse environmental impacts are disclosed. To the extent that specific discretionary actions or program elements could potentially alter the conclusions in the 2008 FGEIS and subsequent technical memoranda, the SEIS focuses on evaluating the potential significant adverse impacts of those actions or elements. The SEIS also identifies and analyzes appropriate mitigation for any significant adverse environmental impacts.

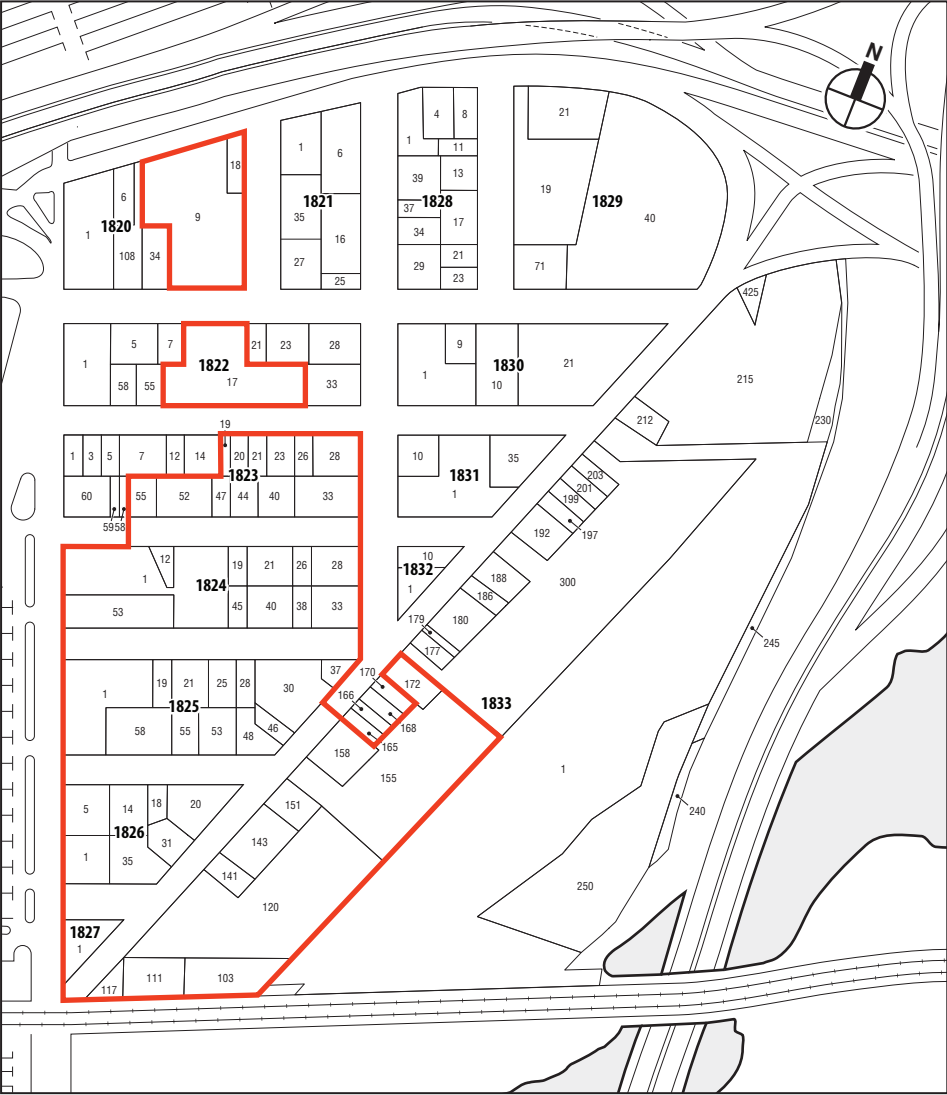

While the 2008 FGEIS was prepared in accordance with the guidelines set forth in the 2001 *CEQR Technical Manual*, this SEIS addresses the updated guidance and analysis methodologies provided in the 2012 *CEQR Technical Manual*.

REASONABLE WORST-CASE DEVELOPMENT SCENARIO

The proposed program detailed above, along with the potential development analyzed in the 2008 FGEIS for Lot B, is analyzed as the reasonable worst-case development scenario (RWCDs) in the SEIS. It is currently anticipated that the assemblage of land within the Special Willets Point District for the Phase 1A and Phase 1B developments could take one of two forms, as shown in **Figure S-7**. As shown, both assemblage options would include Block 1823 (Lots

Assemblage Option 1

Assemblage Option 2

19, 20, 21, 23, 26, 28, 33, 40, 44, 47, 52, and 55), Block 1824, Block 1825, Block 1826, Block 1827, Block 1833 (Lots 117, 111, 103, 120, 141, 143, 151, 155, 158, and 172), and Block 1822, Lot 17. In addition to the land common to the two assemblage options, Assemblage Option 1 would include the remaining lots on Block 1823, that is Lots 1, 3, 5, 7, 12, 14, 58, 59, and 60. Assemblage Option 2 would not include the land specific to Assemblage Option 1, but would instead include Lots 9 and 18, on Block 1820. In either scenario, the assemblage would total approximately 23 acres. However, for the purposes of a conservative analysis, the SEIS assumes that all of the potential project site area, totaling 25 acres, would be utilized in Phase 1A and 1B development. For Phase 2, the SEIS assumes that all land comprising both assemblage options taken for Phases 1A and 1B has been developed.

The SEIS analyzes the potential development of parking, retail, and office uses on Lot B, a portion of the CitiField leasehold along Roosevelt Avenue. The 2008 FGEIS anticipated that if the Willets Point Development Plan were approved and the District were redeveloped into a new mixed-use community and regional destination, additional development could occur on this lot. Any such program for Lot B would require an amendment to the current lease agreement and discretionary approval by IDA, acting through the New York City Department of Parks and Recreation (DPR), which administers the IDA lease. This action would be the subject of a separate environmental review process subject to SEQRA and/or CEQR. This potential development is not part of the proposed program, and no specific development plans have been proposed; however, for the purposes of a conservative analysis, a conceptual program for Lot B will be analyzed as part of the RWCDS. The conceptual program to be analyzed is the same as proposed in the 2008 FGEIS: 184,500 sf of retail use and 280,000 sf of commercial use, which could include a one-story retail structure and a 10-story office building. The existing VIP/ADA (Americans with Disabilities Act) parking spaces on Lot B are assumed to be replaced on site; accessory parking for the Lot B development is assumed to be included on Lot D, as analyzed in the 2008 FGEIS. For the purposes of the RWCDS, it is assumed that this development would be completed by 2032.

STUDY AREAS

Each technical study must address impacts within an appropriate geographical area. These “study areas” vary depending on the technical issue being addressed. In most cases, the study areas for the SEIS for impacts arising from the proposed project are different than those presented in the 2008 FGEIS because the geographic extent of the project site for the SEIS will extend west of West 126th Street.

FUTURE ANALYSIS YEAR AND BASELINE CONDITIONS

The analysis of the proposed project is performed for the expected year of completion of full build-out of the project, which is anticipated to be 2032. However, some project elements are anticipated for completion by 2018 and 2028, and those elements could result in significant adverse impacts prior to completion of the full development program. While the construction of the Phase 1B program is anticipated to take four years, the buildings within the Special Willets Point District are not expected to be ~~occupied~~ constructed until the Van Wyck Expressway ramp improvements have been completed, which is slated to be in 2024. Therefore, three future baseline conditions are examined under the “future without the proposed project” in all technical chapters: the 2018, 2028, and 2032 No Action scenarios. For the purposes of a conservative analysis, this SEIS assumes that the existing uses on the project site would be maintained in each of the three No Action scenarios.

E. PROBABLE IMPACTS OF THE PROPOSED PROJECT

LAND USE, ZONING, AND PUBLIC POLICY

Consistent with the 2008 FGEIS and subsequent technical memoranda, this analysis finds that the proposed project would not result in any significant adverse impacts to land use, zoning, or public policy.

As anticipated in the 2008 FGEIS, the proposed project would dramatically change land uses in the Special Willets Point District by replacing predominantly low-density, auto-related, and industrial uses with a new mixed-use neighborhood. The proposed project also would constitute a significant change for the Willets West portion of the project site by replacing a surface parking field with a new entertainment and retail center of approximately 1.4 million gross square feet (gsf) (approximately one million square feet (sf) of gross leasable area). New structured parking facilities would be built on the South Lot and Lot D to accommodate a portion of the parking for Mets patrons relocated from the Willets West surface parking field.

While the proposed project would result in significant land use changes on the project site, the effects of this change would not be adverse. The District would create a dynamic, sustainable community by integrating regional attractions and residential, retail, and other uses within a network of pedestrian-scaled streetscapes. The previously approved zoning regulations would continue to determine elements such as the placement of uses within the District, building heights and setbacks, street controls (i.e., mandatory intersections and street types), streetscape design, and basic site planning and design provisions. The Willets West portion of the project would create a regional entertainment and retail destination center that would support and be compatible with the new uses in the District as well as uses in the surrounding area.

Consistent with the 2008 FGEIS, the proposed project represents a critical step in implementing the 2004 Downtown Flushing Development Framework, a land use and economic planning strategy for the growth of Downtown Flushing, the Flushing waterfront, and adjacent areas. The District would be developed pursuant to the zoning regulations approved in 2008 and pursuant to the proposed zoning text amendment, and the proposed project would advance a number of the Framework's fundamental goals, including the creation of a regional destination that would enhance economic growth in Downtown Flushing; improvement of environmental conditions; and integration of new development with surrounding amenities, including the Flushing Bay Promenade, CitiField, Flushing Meadows-Corona Park, and Downtown Flushing. The proposed project would be consistent with and vital to the advancement of several of the goals of PlaNYC, which aim to create a more sustainable New York by the year 2030. The proposed project would also be consistent with the coastal policies set forth in the New York City Waterfront Revitalization Program (WRP).

SOCIOECONOMIC CONDITIONS

Consistent with the 2008 FGEIS and subsequent technical memoranda, this analysis finds that the proposed project would not result in any significant adverse impacts to socioeconomic conditions. The following summarizes the conclusions for each of the six CEQR areas of socioeconomic concern.

DIRECT RESIDENTIAL DISPLACEMENT

The proposed project would result in the same direct residential displacement as identified in the 2008 FGEIS (one residential unit/household located in the District); there are no residential units located on the expanded portions of the project site. Therefore, the SEIS does not require further assessment of potential socioeconomic impacts due to direct residential displacement.

INDIRECT RESIDENTIAL DISPLACEMENT

A detailed analysis finds that the proposed project would not result in significant adverse impacts due to indirect residential displacement. The proposed project would develop more total residential units (5,850 vs. 5,500) and more affordable housing (35 percent of units) than analyzed in the indirect residential displacement analysis of the 2008 FGEIS, which considered the Convention Center Scenario. The increase in the affordable housing percentage was analyzed in the subsequent Technical Memorandum No. 2 (2008), and no significant adverse impacts were identified related to that change.

The increase in the number of residential units as analyzed in the SEIS does not alter the 2008 FGEIS finding that the District is geographically separated from the at-risk population, limiting its potential to influence surrounding residential trends. Residential markets within the study area are similar to the markets described in the 2008 FGEIS; as with the FGEIS, the SEIS finds that these geographically separated communities would experience upward rent pressure with or without the proposed project due to planned projects that are within their distinct residential markets. Similar to the 2008 FGEIS, the SEIS finds that although the population that would be introduced by the proposed project may include a larger proportion of households at higher incomes as compared with the existing study area population, the proposed project's 2,048 affordable housing units would ensure that a substantial portion of the new population would have incomes that would more closely reflect existing incomes in the study area.

DIRECT BUSINESS DISPLACEMENT

The proposed project would result in the same direct business displacement identified and analyzed in the 2008 FGEIS and subsequent technical memoranda, and market conditions are similar to those described in the 2008 FGEIS; there are no businesses located in the expanded portions of the project site.¹ Therefore, the SEIS does not require further assessment of potential socioeconomic impacts due to direct business displacement.

The 2008 FGEIS found that the Willets Point Development Plan would displace approximately 260 businesses and 1,711 employees associated with those businesses. As of December 2012, there were an estimated 220 businesses and 1,353 employees still located within the District portion of the project site. As shown in **Table S-4**, a vast majority of the remaining businesses (193 businesses, or 88 percent) are auto-related, but those businesses employ only 53 percent of the remaining employees. The remainder of the employees works in the 27 non-auto-related businesses.

¹ Any businesses locating in the District since the 2008 FGEIS have voluntarily done so knowing that they could be displaced; therefore, they do not meet the CEQR definition of direct business displacement, which is the involuntary displacement of businesses from a project site.

Willets Point Development

While the timeline for the displacement of any individual business varies depending on its business plans and relocation efforts, overall it is anticipated that by the 2018 Build year all of the 122 remaining businesses currently located in the Phase 1A/Phase 1B portion of the project site would be displaced to accommodate development of Phase 1A. The 98 remaining business located in the Phase 2 portion of the project site would be displaced by the 2028 Build year.

Table S-4
Project Site Employment by Business Type and Sector
December 2012

North American Industry Classification System (NAICS) Economic Sector	Number of Businesses/ Institutions	Percent of Businesses/ Institutions	Number of Jobs	Jobs as a Percentage of Total
Auto-Related Businesses	193	88%	712	53%
Retail Trade (NAICS 44 & 45)	31	14%	210	16%
Repair & Maintenance Services (NAICS 811)	153	70%	457	34%
Wholesale Trade (NAICS 42) – <i>scrap yards</i>	4	2%	33	2%
Transportation & Warehousing (NAICS 48)	5	2%	12	1%
Non Auto-Related Businesses	27	12%	641	47%
Construction (NAICS 236 & 238)	6	3%	147	9%
Manufacturing (NAICS 31-33)	5	2%	72	5%
Wholesale Trade (NAICS 42)	7	3%	232	12%
Administrative and Support and Waste Management and Remediation Services (NAICS 56)	5	2%	178	11%
Arts, Entertainment & Recreation (NAICS 71)	0	0%	0	0%
Accommodation & Food Services (NAICS 72)	5	2%	12	1%
Other Services (NAICS 813)	0	0%	0	0%
Total District Businesses	220	100%	1,353	100%
Notes: Employment figures for auto repair and maintenance establishments were derived from AKRF site visits, interviews by Howard/Stein-Hudson, Cornerstone and EDC business interviews, and estimates for businesses based on New York State Department of Labor (DOL) sector averages for Queens County and Dun and Bradstreet.				
Sources: AKRF, Inc., Howard/Stein-Hudson Business Survey, Cornerstone interviews, EDC, DOL				

EDC has contracted with Cornerstone Group, a business relocation expert, to provide relocation assistance and advisory services to impacted businesses in Willets Point. Cornerstone Group has been engaged in outreach to tenant businesses since January 2008 and commenced its most recent round of outreach to affected Willets Point businesses on City-owned property in September 2012. They have already identified several potential relocation sites and will continue to work with business to provide relocation assistance.

EDC retained LaGuardia Community College (LAGCC) to develop a Workforce Assistance Plan for District workers who are directly displaced by the project. The program provides displaced workers with services such as job training and job placement services, ESL and GED coursework, and additional social services. To date, there have been over 600 program participants and the program is ongoing.

INDIRECT BUSINESS DISPLACEMENT DUE TO INCREASED RENTS

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. The SEIS preliminary assessment finds that these additional commercial and entertainment uses would not introduce trends that are substantially different from those identified in the 2008 FGEIS, and would not result in significant indirect business displacement due to increased rents.

While the proposed project's uses would be a substantial addition to the ¾-mile study area, they would not be new types of uses within the study area, and therefore would not introduce a new trend that could substantially alter economic patterns. The study area is already experiencing a trend toward increased retail and residential development. The proposed project's additional retail would serve existing residents, and would accommodate future consumer demand introduced by residents of planned developments and the proposed project. The uses, residents, and workers introduced by the proposed project represent a continuation of existing trends, rather than a new trend that would place upward pressure on office rents in the study area. Similarly, there are already destinations in the study area that offer entertainment and/or recreational opportunities, including Flushing Bay Promenade, CitiField, USTA National Tennis Center, Flushing Meadows-Corona Park, College Point Multiplex Theater, and Downtown Flushing.

INDIRECT BUSINESS DISPLACEMENT DUE TO RETAIL MARKET SATURATION

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. Similar to the 2008 FGEIS, the SEIS analysis finds that the proposed project, including these additional proposed retail uses, would not substantially raise retail market capture rates within a 5-mile Primary Trade Area and, therefore, would not have the potential to adversely affect competitive stores in the Primary Trade Area.

The SEIS preliminary assessment finds that the retail introduced by the proposed project would result in trade area capture rates well below 100 percent by 2032, which is the *CEQR Technical Manual* threshold requiring detailed analysis.¹ However, to maintain a scope of analysis consistent with that performed for the 2008 FGEIS, the SEIS includes a detailed analysis of indirect business displacement due to retail market saturation.

Similar to the analysis in the 2008 FGEIS, the detailed analysis focuses on grocery stores in the immediate vicinity of the proposed project, in particular, because grocery stores generally serve as anchors for retail concentrations, and the proposed project could introduce stores offering products that substantially overlap with typical grocery store offerings. In addition, the SEIS detailed analysis examines the future viability of anchors in regional retail centers, including movie theaters and restaurants, because the Willets West component of the proposed project would constitute a major new shopping and entertainment center, adding destination retail space to the Primary Trade Area.

The detailed analysis finds that the amount of indirect business displacement due to competition from the proposed project would be minimal, is not expected to jeopardize the viability of any neighborhood retail strips, and is not expected to diminish the level of services provided. Therefore, the proposed project would not result in significant adverse impacts due to retail market saturation.

¹ The 2008 FGEIS analysis of indirect business displacement due to competition was performed under the 2001 CEQR Technical Manual, which required detailed analysis even when capture rates were below 100 percent. The 2012 CEQR Technical Manual does not require similar detailed analysis if capture rates with the proposed project do not exceed 100 percent.

ADVERSE EFFECTS ON A SPECIFIC INDUSTRY

The proposed project would result in the same direct business displacement as analyzed in the 2008 FGEIS, and would not present any new or different uses that would alter the findings of the 2008 FGEIS with respect to potential effects on the auto industry or industries dependent on auto repair. Therefore, no further assessment of this issue of concern is required for the SEIS.

COMMUNITY FACILITIES

The analysis ~~provided below~~ regarding potential indirect effects to health care facilities and police and fire protection facilities concludes that—consistent with the conclusions of the 2008 FGEIS—the proposed project would not result in any significant adverse impacts on these community facilities and services.

The analysis of potential indirect effects on elementary, intermediate, and high schools finds that the proposed project would not result in any significant adverse impacts on high schools. In order to accommodate all of the project-generated elementary and intermediate school students, thereby avoiding any significant adverse impacts, the Queens Development Group, LLC (QDG) would coordinate with the School Construction Authority (SCA) to determine whether the public school space currently planned as part of Phase 1B would be sufficient to accommodate all of the school children generated by the proposed project by 2028. Provision of the school in Phase 1B would be ensured through a contractual agreement. If necessary, the school spaces would be expanded, and corresponding reductions in square footage would be made elsewhere in the development program. For Phase 2, the New York City Economic Development Corporation (EDC) would require as part of the developer's agreement that the designated developer similarly coordinate with SCA.

The analysis of potential indirect effects on library services finds that the holdings per resident ratio for the combined study area would decrease from 3.03 under the No Action condition to 2.80 with the proposed project in 2032. This ratio would decrease to 5.02 for the Flushing Library and to 0.69 for the Corona Library. For both the Flushing Library and Corona Library, the catchment area population increase would exceed five percent, which may represent a significant adverse impact on library services according to the *CEQR Technical Manual*. However, as noted above, many of the residents in the catchment areas also reside within the catchment areas for other nearby libraries and would also be served by these libraries, residents of the study area would have access to the entire Queens Library system through the inter-library loan system, and would also have access to libraries near their places of work. In consideration of the above, the lead agency, in consultation with the Queens Public Library, has determined that the additional population introduced by the proposed project would impair the delivery of library services in the study area in 2032. Therefore, Phase 2 of the proposed project would result in a significant adverse impact on library services. To mitigate this impact, adequate space¹ within the 125,000 square feet of as-yet-unprogrammed community facility space in the program for Phase 2 ~~could potentially~~ would be made available to be utilized as a branch library or auxiliary facility for the Queens Library system, or additional volumes or programs to accommodate new users could be provided if adequate space in nearby branches exists. Although no developer has yet been

¹ In other projects, 15,000–20,000 square feet of community facility space has been adequate for the operation of a branch library.

designated for Phase 2, the provision of additional library space in Phase 2 would be based on further consultation with Queens Public Library and the lead agency.

The analysis of indirect effects on child care facilities finds that the proposed project may result in significant adverse impacts on publicly funded child care facilities in 2028. Therefore, consistent with the conclusions of the 2008 FGEIS, to mitigate the potential impact on child care facilities that could occur by 2028, the QDG (i) would consult with the New York City Administration for Child Services (ACS) to determine whether adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site is the appropriate way to meet demand for child care services generated by the proposed project; and (ii) would, as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site. EDC would require, as part of the developer's agreement, that the designated developer of Phase 2 similarly consult with ACS to determine the appropriate way to meet demand for child care services generated by development in the District by 2032 and would as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site.

OPEN SPACE

This analysis finds that the RWCDs would not result in significant adverse open space impacts that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

DIRECT EFFECTS

By 2018, the Willets West portion of the proposed project would be constructed upon 30.7 acres of the surface parking lot west of CitiField, and one of the CitiField parking lots along Roosevelt Avenue (South Lot) would also be developed. While this land is mapped as parkland, it does not function as recreational open space. The land was occupied by Shea Stadium and associated parking and circulation space until it was replaced by CitiField in 2009, and it is now occupied exclusively by surface parking. There is one event—the Major League Wheelchair Softball Tournament—that is held in this area; however, this is not an event that occurs on a constant and regular basis for designated daily periods. This parking area is therefore not considered a public open space use as defined under CEQR. Furthermore, the Major League Wheelchair Softball Tournament would be relocated to the Special Willets Point District in Phase 1A of the proposed project. Therefore, developing this mapped parkland has no direct effect on the adequacy of open space for the study area residential and non-residential populations.

The proposed project would activate the Willets West area, making the area more appealing to residential and non-residential populations and improving connections between the study area populations and the Flushing Bay Promenade. It is anticipated that some of the trees within the Willets West portion of the project site would require removal during construction, as would trees within the Lot B area. Tree replacement would be conducted in conformance with DPR requirements, including approval from DPR's Queens forestry division. The portions of the project to be constructed by 2028 and 2032 also would have no direct effect on the adequacy of open space for the study area residential and non-residential populations.

The proposed project would not have any adverse impacts on existing open space in terms of air quality, noise, or shadows. The World's Fair Marina Park, which was predicted in the 2008 FGEIS to experience a significant adverse noise impact during the Saturday mid-day time period, is no longer expected to experience a significant adverse impact.

Willets Point Development

The proposed project would add to the inventory of open space in the study area. During Phase 1A of the proposed project, the parking area within the Special Willets Point District would be converted to active recreational use a minimum of six months per year. Permanent publicly accessible open space would be built as part of Phase 1B and Phase 2, in accordance with the District's zoning requirements, as residential populations are introduced. Phase 1B would include approximately six acres of new publicly accessible open space, approximately 3.5 of which would subsequently be developed with new structures in Phase 2. Phase 2 would create another 5.5 acres of open space, for a total of 8 acres of publicly accessible open space at the conclusion of the development of the proposed project.

INDIRECT EFFECTS

Although the development of the proposed project would include the creation of publicly accessible open space, because it would also introduce demand from a new population the RWCDS would result in a decrease in total, active, and passive open space ratios in the residential study area and a decrease in total and passive open space ratios in the non-residential study area. These decreases would not result in a significant adverse open space impact. Open space ratios would remain near or above the recommended City guidelines, with the exception of the active open space ratio, which would decrease from 1.80 acres per 1,000 residents in the 2018 No Action condition to 1.54 in the 2028 With Action condition and 1.31 in the 2032 With Action condition. The total open space ratio would remain above the recommended City guideline until 2032, when it would decrease to 2.46, falling slightly below the guideline of 2.5 acres per 1,000 residents. The amount of active open space available in the study area during Phase 1A would be higher than indicated by the ratios, due to the presence of the interim active recreational use to be provided within the District, which was not considered in the open space ratios. Upon completion, the RWCDS would include a minimum of 8 acres of publicly accessible open space, including an approximately two-acre park developed with primarily active recreational uses.

The RWCDS would not result in a significant adverse open space impact during any of the three analysis years. The proposed project would introduce substantial new open space, and study area residents would continue to have access to the portions of Flushing Meadows-Corona Park and the Flushing Bay Promenade that fall just outside of the residential study area's boundaries. Further, QDG would work to incorporate ground-level, active open space and other recreational resources such as rooftop and interior programming of recreational amenities into the project design for Phase 1B, and EDC would encourage through its formal Request for Proposals (RFP) process the future developer of Phase 2 to incorporate similar features into the Phase 2 development. While these recreational amenities may be available only to tenants and residents of the site—and thus have not been included in the quantitative analysis—these amenities would help offset the burden on public active and passive resources resulting from the introduction of new users on the project site.

SHADOWS

The analysis concluded that the proposed parking structure in the South Lot would cast new shadows early in the mornings in all seasons onto adjacent traffic islands and a portion of an area containing trees, but that the shadows would be limited in extent and duration and would not cause significant adverse shadow impacts to these sections of Flushing Meadows-Corona Park. The Willets West development would cast new shadows of very limited extent and duration on nearby landscaped traffic islands in the winter only, and these would not cause significant

adverse shadow impacts. Therefore, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in any significant adverse shadows impacts.

HISTORIC AND CULTURAL RESOURCES

This analysis finds that the proposed project would not result in significant adverse impacts related to historic and cultural resources that were not addressed in the 2008 FGEIS or subsequent technical memoranda. Consistent with the findings in the 2008 FGEIS, the development that would occur within the Special Willets Point District during Phase 2 of the proposed project would have a significant adverse impact on the former Empire Millwork Corporation Building.

URBAN DESIGN AND VISUAL RESOURCES

This analysis concludes that the proposed project would not have any significant adverse impacts related to urban design and visual resources, consistent with the findings of the 2008 FGEIS and subsequent technical memoranda.

NATURAL RESOURCES

This analysis finds that existing conditions and potential impacts to natural resources are largely the same as were addressed in the 2008 FGEIS and subsequent memoranda, and that the RWCDs would not result in significant adverse impacts to floodplains, wetlands, groundwater, terrestrial resources, aquatic resources and Essential Fish Habitat (EFH), threatened or endangered species, species of special concern, or rare ecological communities. The 100-year floodplain within and adjacent to the study area is affected by coastal flooding rather than local flooding, and therefore, would not be affected by construction or regrading/filling that would occur as part of the RWCDs; building designs would be consistent with *New York City Building Code* requirements for construction within the 100-year floodplain and any future changes to these requirements that may be made on the basis of the newly-released FEMA ~~Advisory Base Flood Elevations~~ Best Available Flood Hazard Data (BAFHD). Prior to commencement of construction for each phase of the project, the project sponsor will work with the Mayor's Office of Environmental Coordination (MOEC) to develop a plan for resilience of the proposed area to be developed in that phase from future flood levels, considering the types of uses proposed. No wetlands are present on or adjacent to Willets West or the South Lot, and wetland boundaries in the vicinity of the District, Lot B, and Lot D are as described in the 2008 FGEIS. No significant adverse impacts to wetlands would occur as a result of the RWCDs. Terrestrial natural resources, such as vegetation and wildlife, are largely the same as described in the 2008 FGEIS, and the RWCDs would have no significant adverse impacts to these resources, including threatened or endangered species. Consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts to groundwater quality. With the implementation of erosion and sediment control measures, water quality, aquatic biota, and EFH of Flushing Bay would not be affected by land-disturbing construction activities. No in-water construction would occur. The proposed stormwater infrastructure for the RWCDs may improve stormwater quality above the existing condition by addressing existing chronic flooding, improving the quality of the soil substrate of the site, providing direct drainage to storm sewers, and incorporating sustainable design features, where feasible, to reduce the discharge volume. Overall, no significant adverse impacts to natural resources would result from the RWCDs.

HAZARDOUS MATERIALS

This analysis finds that, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts related to hazardous materials.

As described below, Phase I Environmental Site Assessments (ESA) have been performed for the entire project site. These identified the potential for contamination due to current and past usage:

- **Special Willets Point District:** sampling undertaken as part of previous Phase II ESAs confirmed that contamination is present and is expected to be widespread.
- **Lot D:** Tires and apparently empty 35-gallon drums were present on Lot D. Evidence of a potential underground storage tank was observed. However, the Phase I ESA found no registered historical or current petroleum storage tanks, which indicates that the tank may have been installed/operated prior to tank registration requirements or may have been of too small a capacity to require registration. Prior to development, a Phase II ESA would be performed for Lot D to assess potential contamination and assist in preparation of any necessary remedial plans and health and safety procedures.
- **Lot B:** Subsurface sampling identified fill material (including cinders, wood, brick, metal, and asphalt) overlying marsh deposits. This was consistent with historical information regarding prior conditions and uses. The soil sampling did not identify significant contamination (the results were consistent with those usually found in historical fill materials in New York City). Similarly, the shallow groundwater sampling identified some levels (generally of metals) above the most stringent (drinking water) standards but these were consistent with the levels of metals found in the soil samples of the fill material. The soil gas sampling found elevated levels of methane (potentially attributable to the marsh deposits).
- **Willets West and South Lot:** The Phase I ESA indicated that these portions of the project site were also part of the much larger “ash dump” in the early part of the 20th century. Around 1950, Willets West was paved and used for parking until 1964, when Shea Stadium opened on the property. The South Lot has been used for parking since the mid 1960s. In 2009, Shea Stadium was demolished and has since been used for parking with multiple small ticketing structures. The Phase I ESA found no evidence of historical or current petroleum storage tanks or other historical uses of concern. Prior to development, a Phase II ESA would be performed for the Willets West and South Lot areas to assess potential contamination and assist in preparation of remedial plans, if necessary, and health and safety procedures to be implemented during construction.

By implementing investigation and remediation measures including appropriate engineering/institutional controls into the development, as well as incorporating health and safety procedures into the construction, it is expected that no potential exposure or significant adverse impacts related to hazardous materials would occur during or after construction of the proposed project. Construction of the proposed project would involve both demolition of all existing structures (some of which are believed to contain asbestos containing materials, lead-based paint, and polychlorinated biphenyls containing electrical components) and a variety of earthmoving/excavating activities that would encounter subsurface contamination (e.g., petroleum, solvents, polychlorinated biphenyls, or other contaminants associated with the area’s historical filling), particularly within the District. To avoid the potential for significant adverse

impacts related to hazardous materials the proposed project would include appropriate health and safety (e.g., dust control and air monitoring) and comprehensive investigative/remedial measures (e.g., delineating and excavating contaminated soils and disposing of them off site at an appropriately licensed facility) that would be undertaken in conjunction with the excavation and disturbance of fill material. Understanding that the entire area includes ash fill and that within the project site fill material would remain, residual soil and groundwater contamination would need to be accounted for in any new development. Engineering controls to address the residual contamination can include a variety of measures including but not limited to capping surfaces, groundwater controls to prevent migration, and systems beneath buildings to prevent infiltration of soil vapor.

While development of the District is contemplated to occur in phases, Phase 1A will incorporate a comprehensive site investigation and associated remedial action that will remove areas of significant contamination and prepare the site for development. When subsequent development takes place over or adjacent to these areas, measures will be undertaken to prevent human exposure. These will include stringent measures for dust control, procedures for dewatering, proper handling and disposal or backfill of excavated material and prevention of stormwater pollution from runoff. Additional measures (e.g., the mandatory implementation of appropriate health and safety procedures) will be undertaken to prevent exposure following development during intrusive work and subsurface utility repairs at developed sites.

Institutional controls would be used to ensure that the various measures outlined above would be implemented, all lots in the project site would have restrictions placed on them. Specifically, for the District, these restrictions include the E designations already placed following the 2008 FGEIS and potentially State of New York Brownfield Cleanup Program (BCP) requirements, should any developments enter into this (voluntary) program. For lots outside of the District, the restrictions would be incorporated into the development agreements and/or amended leases for each lot. These lots are and would remain in City ownership.

A Phase II Subsurface Investigation Work Plan and a Health and Safety Plan (HASP) were prepared for the Willets West portion of the project site in February 2013 and submitted to the New York City Department of Environmental Protection (DEP) for review and approval. The Phase II Work Plan and HASP were revised and resubmitted to DEP in June 2013 based on a DEP letter requiring additional testing (dated March 27, 2013), and the revised Work Plan and HASP were approved by DEP in a letter dated July 31, 2013.

WATER AND SEWER INFRASTRUCTURE

This analysis finds that the proposed project would not result in significant adverse impacts to water and sewer infrastructure that were not addressed in the 2008 FGEIS and subsequent technical memoranda. Infrastructure improvements would be required for various phases of the project, as detailed in this section:

PHASE 1A

New 12-inch water mains in 35th Avenue, 126th Street, 127th Street, and Willets Point Boulevard would be constructed as necessary to support the proposed development. For Willets West, a new on-site water loop would be required to tie into existing water main in Roosevelt Avenue.

Willets Point Development

Sanitary sewer infrastructure, either existing or being built by the New York City Economic Development Corporation (EDC), would be adequate to accommodate the Phase 1A development. A 36-inch sanitary sewer, as well two stubbed connections in 126th Street: one 24-inch and one 16-inch, is currently being constructed by EDC. As a part of the proposed project, the 16-inch connection would be extended south along 126th Street by the Queens Development Group, LLC (QDG). Based on current estimates, the 36-inch sanitary sewer under construction, the 24-inch sewer downstream from it, and the 37th Avenue pump station would have sufficient capacity to accommodate the development proposed under Phase 1A. As part of the Phase 1A DEP approval process, QDG would work with DEP to assess the operations of the existing pump station. Based on this assessment, QDG would replace or upgrade components identified as requiring such work as a result of the additional flows associated with the Phase 1A development. Based on measured existing flow to the Bowery Bay Water Pollution Treatment Plant (WPTP) and the projected sanitary flow from the proposed development in Phase 1A, the WPTP would have sufficient capacity to accommodate the proposed project flow.

A 7.5-foot by 5-foot box storm sewer currently under construction by EDC would be extended south along 126th Street by QDG as part of the proposed project to accommodate Phase 1A development within the Special Willets Point District. For Willets West and the other sites, existing infrastructure would be sufficient to convey stormwater runoff.

PHASE 1B

Consultation with DEP would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required to support the Phase 1B development. As assumed in the 2008 FGEIS, the existing 72-inch water main within Willets Point Boulevard would remain in place and a permanent easement, mapped on the City map, would be provided to enable DEP access to this water main. A grade change and replacement of portions of the water main, contemplated in TM#4 would not be required.

Based on current estimates, the 36-inch sanitary sewer currently under construction would have sufficient capacity to accommodate the development proposed under Phase 1B. Upgrades to the 37th Avenue pump station and its force main would likely be required for Phase 1B development. If needed to support Phase 1B development, QDG would fund the 37th Avenue pump station upgrade, at the time when the need arises. It is anticipated that the upgrade would occur within the existing city land or rights-of-way. Verification of this requirement by DEP will be obtained prior to Phase 1B development. Based on measured existing flow to the Bowery Bay WPTP and the projected sanitary flow from the proposed development through Phase 1B, the WPTP would have sufficient capacity to accommodate the proposed project flow.

Stormwater and sanitary sewer infrastructure constructed would be sized in accordance with the DEP-approved amended drainage plan (ADP) prepared by QDG.

PHASE 2

For the District, consultation with DEP would be required to determine water supply requirements for Phase 2 of the proposed project. Additional internal water service would likely be required to support the proposed development in 2032. Additionally, consultation with DEP would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required to support the Phase 2 development, if not already constructed in a prior phase. For all other sites, water service would remain as constructed.

For the District, new sanitary sewer trunk mains would be required in Northern Boulevard 126th Street, and Roosevelt Avenue. These sewers would be sized in accordance with the ADP that would be developed. Based on current estimates, the 36-inch sanitary sewer currently under construction would have sufficient capacity to accommodate the development proposed with the full development through Phase 2. Per the draft ADP, upgrades to the 37th Avenue pump station and its force main would be required for Phase 2. Specifically, the operating capacity of the 37th Avenue pump station (currently 3,450 gpm) would need to be upgraded to 8,400 gpm. If not previously performed upgrades to the 24-inch sewer under the Grand Central Parkway, the 37th Avenue pump station and its associated downstream force main would be required, and would be funded by the developer of Phase 2. These upgrades would be in conformance with the DEP approved ADP. Based on measured existing flow to the Bowery Bay WTP and the projected sanitary flow from the proposed development through Phase 2, the WTP would have sufficient capacity to accommodate the proposed project flow.

For the District, new storm sewers would be required in Northern Boulevard, 126th Street, and Roosevelt Avenue. These sewers would be sized in accordance with the ADP developed for Phase 2. In addition, a 60-inch outfall would be required in 127th Street for Phase 2.

SANITATION AND SOLID WASTE

This analysis finds that the RWCDS would not result in significant adverse impacts to solid waste and sanitation that were not addressed in the 2008 FGEIS or subsequent technical memoranda.

While the RWCDS would create new demands on solid waste and sanitation services, the municipal systems serving the project site area have adequate capacity to meet the projected increases in demand. The New York City Department of Sanitation (DSNY), which collects solid waste and recyclables, is anticipated to provide municipal solid waste and sanitation services to the District. Private carters currently and will continue to provide these services to non-residential users. The RWCDS would cumulatively increase the volumes of solid waste and recyclables, but would not affect the delivery of these services, place a significant burden on the City's solid waste management services (public or private), or require any amendments to the City's solid waste management objectives as stated in the SWMP. As disclosed in the 2008 FGEIS, the RWCDS would displace waste transfer businesses from the District by 2032, but this displacement would not have a significant adverse impact on the waste and sanitation services in Queens or in New York City.

ENERGY

Consistent with the findings of the 2008 FGEIS and subsequent technical memoranda, this analysis concludes that the proposed project would not result in significant adverse impacts on energy demand and infrastructure. The cumulative annual energy consumption that would result from the RWCDS, including the potential future development on Lot B, would be 1,952,503 million BTUs. Phase 1A and 1B are subject to Local Law 86 of 2005 (see New York City Charter section 224.1) and the project sponsor would comply with the requirements thereof. To the extent Local Law 86 of 2005 applies to any portion of Phase 2, the City would further ensure that the sponsor for Phase 2 complies with the requirements thereof. Accordingly, in Phase 1A, the retail buildings, including the proposed development on the Willets West site, will be designed and constructed to achieve Leadership in Energy and Environmental Design (LEED) silver certification for core and shell (LEED-CS), and the hotel building will be designed and

constructed to achieve LEED silver certification for new construction (LEED-NC). In Phases 1B and 2, as set forth in the FGEIS and reiterated in Technical Memorandum #4, all portions of the project within the Willets Point Special District will be required to achieve LEED for neighborhood development (LEED-ND) certification. Phase 1B buildings will also comply with all the applicable requirements of Local Law 86 of 2005. Specifically, retail, hotel, community facility and office buildings will be designed and constructed to achieve LEED silver certification pursuant to the LEED rating system that is most appropriate under Local Law 86 (see Section 10-02 of chapter 10 of title 43 of the Rules of the City of New York). To meet the requirements of LEED and the energy cost reduction requirements of Local Law 86 of 2005 that are applicable to the project under NYC Charter section 224.1(b)(2)(ii), energy efficiency measures would be incorporated into building designs, as described in this chapter. The requirements of Local Law 86 of 2005 and the commitments set forth in this chapter would be incorporated into the development agreements and/or amended lease agreements. The provisions of the development agreements and/or amended lease agreements, relating to substance and enforceability of these commitments, would be subject to approval by Mayor's Office of Environmental Coordination.

TRANSPORTATION

TRAFFIC AND PARKING

As was found in the FGEIS, the proposed project is expected to be a significant traffic generator on both the highways surrounding the project site—including the Grand Central Parkway, the Van Wyck Expressway, and the Whitestone Expressway—and the local street network over the course of its three buildout phases. The With Action volume increments generated by the proposed project would be as follows:

Phase 1A of the project is expected to generate 883 vehicles per hour (vph) in the AM peak hour, 2,517 vph in the midday peak hour, 2,618 vph in the PM peak hour on a typical weekday without a Mets home game, and 3,132 vph in the Saturday midday peak hour on a non-game weekend. For peak hours with a Mets home game, the proposed project is expected to generate 2,324 vph in the weekday PM (evening) pre-game peak hour, 2,313 vph in the Saturday afternoon pre-game peak hour, and 2,063 vph in the Saturday evening post-game peak hour.

With the completion of Phase 1B, 2,649 vehicles per hour (vph) would be generated in the AM peak hour, 5,152 vph in the midday peak hour, 5,420 vph in the PM peak hour on a typical weekday without a Mets home game, and 5,855 vph in the Saturday midday peak hour on a non-game weekend.

For peak hours with a Mets home game, the proposed project is expected to generate 4,194 vph in the weekday PM (evening) pre-game peak hour, 4,576 vph in the Saturday afternoon pre-game peak hour, and 4,037 vph in the Saturday evening post-game peak hour.

With full buildout at the completion of Phase 2, including the potential future development of Lot B, 4,533 vehicles per hour (vph) would be generated in the AM peak hour, 7,551 vph in the midday peak hour, 8,361 vph in the PM peak hour on a typical weekday without a Mets home game, and 8,740 vph in the Saturday midday peak hour on a non-game weekend. For peak hours with a Mets home game, the proposed project is expected to generate 6,339 vph in the weekday PM (evening) pre-game peak hour, 6,981 vph in the Saturday afternoon pre-game peak hour, and 6,445 vph in the Saturday evening post-game peak hour. This includes volume increment generated by the proposed project and the Lot B development.

Future baseline (future No Action) volumes, to which the traffic generated by the proposed project and Lot B would be added, and future levels of service are expected to be significantly worse than existing conditions due to background traffic growth plus traffic generated from additional background development projects. Traffic generated by the proposed project would be in addition to high baseline volumes and poor levels of service at many of the analysis intersections and along key sections of the highway network.

As a result, by Phase 1A, the proposed project is expected to have significant traffic impacts at 15 of the ~~29~~ 32 intersections analyzed, both signalized and unsignalized, for the future With Action condition in the weekday AM peak hour, ~~17~~ 16 of ~~29~~ 32 in the weekday midday peak hour, and 20 of ~~29~~ 32 in the weekday PM and Saturday midday non-game peak hour. On game days, ~~24~~ 23 of ~~29~~ 32 intersections analyzed would have significant traffic impacts during the PM pre-game weekday peak hour, ~~17~~ 19 of ~~29~~ 32 intersections analyzed would have significant traffic impacts during the Saturday pre-game peak hour and ~~19~~ 21 of ~~29~~ 32 intersections analyzed would have significant impacts during the Saturday post-game peak hour.

In Phase 1B, the proposed project is expected to have significant traffic impacts at 19 of the ~~30~~ 33 intersections analyzed in the weekday AM peak hour, ~~20~~ 21 of ~~30~~ 33 in the weekday midday peak hour, ~~22~~ 21 of ~~30~~ 33 in the weekday PM peak hour, and ~~25~~ 24 of ~~30~~ 33 in the non-game-Saturday midday peak hour. On game days, 22 of ~~30~~ 33 intersections analyzed would have significant traffic impacts during the PM pre-game weekday peak hour, ~~20~~ 21 of ~~30~~ 33 intersections analyzed would have significant traffic impacts during the Saturday pre-game peak hour and ~~24~~ 23 of ~~30~~ 33 intersections analyzed would have significant impacts during the Saturday post-game peak hour.

By full buildout in Phase 2, including the potential future development of Lot B, the proposed project is expected to have significant traffic impacts at ~~22~~ 23 of the ~~34~~ 34 intersections analyzed in the weekday AM peak hour, and ~~26~~ 28 of ~~34~~ 34 in the weekday midday peak hour, ~~29~~ 29 of ~~34~~ 34 in the weekday PM peak hour, and ~~27~~ 27 of ~~34~~ 34 in the Saturday midday non-game peak hours. During the PM pre-game weekday peak hour, ~~25~~ 28 of ~~34~~ 34 intersections analyzed would have significant traffic impacts, and during the Saturday pre-game and post-game peak hours, ~~23~~ 25 of ~~34~~ 34 intersections analyzed would have significant impacts.

Some sections of the highway mainlines and several ramp junctions would incur level of service degradations and be significantly impacted. In Phase 1A, ~~three~~ five of the seven highway mainline locations analyzed (including the westbound Grand Central Parkway and the southbound Whitestone Expressway) and five of the 12 ramp locations would be significantly impacted during at least one of the seven peak analysis hours. In Phase 1B, five of the seven highway mainline locations analyzed (including both directions of the Grand Central Parkway and Whitestone and Van Wyck Expressways) and seven of the 12 ramp locations would be significantly impacted during at least one peak hour. In Phase 2, ~~five~~ four of the seven highway mainline locations analyzed (including the westbound Grand Central Parkway, and both directions of the Whitestone and Van Wyck Expressways) and ~~eight~~ seven of the 12 ramp locations would be significantly impacted during at least one peak hour.

Under Phase 2 for the proposed project (i.e., full buildout conditions), the number of significantly impacted intersections would be approximately the same or somewhat higher as compared to the 2008 FGEIS. The magnitude of delays experienced would be higher at many locations as compared to the 2008 FGEIS. Under Phase 2 for the proposed project, the number of significantly impacted highway sections and ramps, and the magnitude of delays, would

Willets Point Development

generally be higher as compared to the 2008 FGEIS. Potential measures to mitigate these projected significant adverse impacts are described in “Mitigation.”

By its full buildout in Phase 2, the proposed project would provide sufficient new off-street and on-street parking as part of the development to service its peak demand of 5,850 spaces. The redevelopment of the District would include the demapping and realignment of the local street network within the boundaries of the District, which is expected to increase the available on-street parking supply. The proposed project’s expected parking needs would be provided within the immediate area by full buildout, and it is not expected that project-generated traffic would have to seek parking opportunities outside of the area. In all phases, Willets West’s proposed 2,500 accessory parking spaces would be sufficient to meet parking demands generated by the development at Willets West. Under Phase 1A, all project-generated parking demand within the District would be satisfied by accessory parking provided as part of the proposed project. Under Phase 1B, the 2,700 accessory parking spaces that would accompany development in the District would fully satisfy project demand in 2028 except from 2 to 4 PM on Saturday where there would be an additional need of up to approximately 45 spaces. However, this demand is expected to be fully satisfied by available on-street spaces within the District and off-street spaces in facilities within walking distance of the District. For the originally proposed project analyzed in the 2008 FGEIS, the amount of parking to be provided plus available on-street parking was concluded to be similarly sufficient to accommodate the projected parking demand.

In addition to providing accessory parking for project demand, the proposed project would also replace the 4,100 Mets parking spaces in the main CitiField lots to the west of the stadium that would be displaced by the Willets West development. These replacement spaces would be distributed amongst an interim parking facility in the District (2,750 spaces, used as recreational space in the off-season), Lot D/South Lot (950 spaces), and the Willets West development (400 spaces) in Phase 1A, and between Lot D/South Lot (5,495 spaces) and the Willets West development (400 spaces) in Phases 1B and 2. Therefore, Mets parking needs would be accommodated.

TRANSIT AND PEDESTRIANS

Significant adverse transit impacts were identified for the street-level stairways and mezzanine stairway on the north side of Roosevelt Avenue at the Mets-Willets Point subway station, line-haul conditions on the No. 7 subway line, ~~train~~ and the Q19, Q48, and Q66 bus routes. In addition, if NYCT reverts back to its pre-CitiField station operating plan for the Mets-Willets Point subway station, which would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day management strategies. However, additional impacts for the station’s street-level connections and the unpaid zone passageway could occur during game days with this reconfiguration. Between Draft and Final SEIS, no changes to operating plans were announced by NYCT; therefore, any potential changes that may be considered for future implementation will be addressed outside of this environmental review. Significant pedestrian impacts were identified for the east crosswalk at the intersection of Northern Boulevard and 126th Street; the north and west crosswalks at the intersection of Roosevelt Avenue and 126th Street; the north, south, and east crosswalks at the intersection of 34th Avenue and 126th Street; ~~the south crosswalk at the intersection of New Willets Point Boulevard and 126th Street;~~ the north and south crosswalks at the intersection of 37th Avenue and 126th Street; and the north crosswalk at the newly signalized intersection of Roosevelt Avenue and the Lot B driveway. Potential measures to mitigate these projected significant adverse impacts are described in “Mitigation.”

In the 2008 FGEIS and subsequent technical memoranda, significant adverse impacts were identified for the Mets-Willets Point subway station, area bus routes, and pedestrian elements adjacent to the District. Similar or greater impacts have been identified for Phase 2 of the proposed project. In addition, the previous analyses did not identify the significant adverse subway line-haul impact or the additional station impacts associated with potential station reconfiguration by NYCT that had been identified with the current proposed project.

AIR QUALITY

Concentrations of carbon monoxide (CO) and fine particulate matter less than 10 microns in diameter (PM₁₀) due to project-generated traffic at intersections near the project site would not result in any violations of National Ambient Air Quality Standards (NAAQS). It was also determined that CO and PM_{2.5} increments impacts from mobile sources associated with the proposed project would not exceed CEQR *de minimis* criteria. ~~While incremental increases in fine particulate matter less than 2.5 microns in diameter (PM_{2.5}) from mobile sources would be between 2 µg/m³ and 5 µg/m³, based on the frequency and magnitude of the concentrations above 2 µg/m³, which will be subject to further~~ A refined mobile source analysis conducted for PM_{2.5} between DSEIS and FSEIS in consultation with DEP confirmed that there would be no the predicted PM_{2.5} increments would not indicate a significant air quality impact. In addition, impacts due to the proposed project's parking facilities were found to result in no significant adverse air quality impacts.

Based on refined analyses, using conservative assumptions regarding floor area served by a single heating and hot water system stack, there would be no potential for significant adverse air quality impacts from the proposed project's heating and hot water systems (considering buildings proposed for construction in all phases), provided that certain requirements on the fuel type, placement of heating and hot water system stacks, exhaust height, and use of low-nitrogen oxide (low-NO_x) burners are imposed. These restrictions would supersede those identified in the 2008 FGEIS and Technical Memorandum #4. The restrictions reflect the changes to the proposed project since the 2008 FGEIS and subsequent technical memoranda, as well as the promulgation of the 1-hour nitrogen dioxide (NO₂) standard in 2010. A screening level analysis was conducted to assess whether existing auto, manufacturing, and industrial uses that may remain in the area proposed for development in Phase 2, would have the potential to significantly impact the air quality in the area proposed for development in Phase 1A and Phase 1B, which would be occupied by recreational, residential, hotel, open space, and commercial uses. The results of that analysis show that there would be no potential for significant adverse impact on air quality from these sources on the proposed project. Therefore, there would be no potential for a significant adverse impact from stationary sources.

GREENHOUSE GAS EMISSIONS AND CLIMATE CHANGE

As discussed in the following sections, the building energy use and vehicle use associated with the full build-out of the proposed project would result in approximately 150,000 metric tons of carbon dioxide equivalent (CO₂e) emissions per year. The RWCDS, which includes the potential future development on Lot B, would result in approximately 161,000 metric tons of CO₂e emissions from building energy consumption and vehicle use. The overall RWCDS emissions are lower than those presented in Technical Memorandum #4 (TM4), despite the increase in the floor area proposed for development, due to the expected improvement in vehicle efficiency from 2022—the final build year analyzed in TM4, and 2032—the anticipated year of proposed project completion.

Willets Point Development

The proximity of the proposed development to public transportation, its mixed-use nature, and dense design are all factors that contribute to the energy efficiency. To meet the requirements of LEED certification, the energy cost reduction requirements of Local Law 86 of 2005, and to comply with the regulations of the Special Willets Point District, specific measures would be incorporated into the proposed project design, which would decrease the potential GHG emissions and further the GHG reduction goal.

~~As detailed local climate change projections become available and are adopted into the City's infrastructure design criteria, such criteria would be incorporated into the development program. In addition, an engineering study would be prepared prior to commencement of construction that would assess the feasibility of implementing strategies to improve resilience to climate change impacts into the design of the development program, in light of the most current climate change projections. Based on that engineering study, practicable strategies to improve resilience to climate change would be implemented.~~

The proposed project is located within the 100-year floodplain, and therefore, the potential effects of global climate change on the proposed project have been considered. Given that the projections for sea level rise are changing, further measures will be investigated and implemented within the proposed project site to the extent practicable. Prior to the commencement of construction for each phase of the project, the project sponsor will work with MOEC to develop a plan for resilience of the proposed area to be developed in that phase from future flood levels, considering the types of uses proposed. The plan will be designed with the goal of making the project area resilient to end-of-century flood levels in residential areas, and mid-century in other areas.

NOISE

The analysis concludes that noise associated with traffic generated by the proposed project and its associated parking facilities would not be expected to result in any significant increases in noise levels, including at World's Fair Marina Park, which was predicted to experience a significant adverse noise impact in the 2008 FGEIS during the Saturday mid-day (MD) time period. This resulted from slightly less incremental traffic noise generated on streets immediately adjacent to the Park between the No Build and Build scenarios analyzed for the proposed project as compared to the 2008 FGEIS analysis. To meet CEQR interior noise level requirements, the analysis prescribes between 31 and 43 dBA of building attenuation for the proposed project buildings, which is similar to the amount of building attenuation specified in the 2008 FGEIS, except for the buildings included in the proposed project very close to the existing elevated subway tracks along Roosevelt Avenue, which would require greater attenuation than the levels specified in the 2008 FGEIS analysis. Similar to what was predicted in the 2008 FGEIS, noise levels in the newly created open spaces would be greater than the 55 dBA $L_{10(1)}$ prescribed by CEQR criteria, but would be comparable to other parks around New York City and would not constitute a significant adverse impact.

PUBLIC HEALTH

According to the *CEQR Technical Manual*, for most proposed projects, a public health analysis is not necessary. Where no significant unmitigated adverse impact is found in other CEQR analysis areas, such as air quality, water quality, hazardous materials, or noise, no public health analysis is warranted. If an unmitigated significant adverse impact is identified in one of these

analysis areas, the lead agency may determine that a public health assessment is warranted for that specific technical area.

As described in the relevant analyses of this SEIS, during construction, and after completion of construction, the proposed project would not result in unmitigated significant adverse impacts in any of the technical areas related to public health. Therefore, a public health analysis is not necessary, as the proposed project would not result in a significant adverse public health impact.

NEIGHBORHOOD CHARACTER

Consistent with the 2008 FGEIS and subsequent technical memoranda, this analysis finds that the proposed project would not result in any significant adverse impacts to neighborhood character.

The study area has diverse characteristics owing to the varied land uses surrounding the project site. No one defining feature would be considered critical to the character of the neighborhood; rather all the various localized features contribute to it. Taking into consideration the effects of the proposed project on the contributing features, the proposed project would not have a significant adverse impact on neighborhood character. Rather, the proposed project would result in an improvement in neighborhood character, as it would remediate the area and would represent a significant investment to improve the project area's infrastructure. The proposed project would allow for a more comprehensive and continuous neighborhood by linking Flushing and Corona, and would transform the area surrounding CitiField into a thriving new neighborhood and regional destination.

CONSTRUCTION

There would be temporary inconvenience and disruption arising from the construction of the proposed project throughout the Willets Point/CitiField area. As detailed below, construction of the proposed project would result in significant adverse construction impacts related to transportation and historic and cultural resources. Potential mitigation for these significant adverse impacts is discussed in Chapter 21, "Mitigation."

TRANSPORTATION

The construction of the proposed project, from 2014 to 2032, would generate construction worker and truck traffic. Because of the lengthy duration of these activities, an evaluation of construction sequencing and worker/truck projections was undertaken to assess the potential transportation-related impacts. It is expected that the project construction activities would yield considerably less traffic than that projected for the proposed project and that parking and staging needs could be managed primarily within the District, or next to the stadium (for Lot B construction). However, given the high traffic volume in the existing and No Action conditions, and the inclusion of traffic from the project as it is being built out as well as construction traffic, significant adverse traffic impacts could still occur at some of the study area locations during construction. Where impacts during construction may occur, measures recommended to mitigate impacts associated with the proposed project could be implemented early to aid in alleviating congested traffic conditions. At locations where the proposed project is expected to result in unmitigated significant adverse traffic impacts, these impacts could similarly exist during construction.

Construction worker transit trips would occur outside of peak periods of transit ridership and would be distributed and dispersed to the nearby transit facilities, and would not result in any significant adverse transit impacts. However, the significant adverse transit impacts disclosed for the 2032 With Action condition may also occur during peak construction in 2031. Similar mitigation measures as those identified for the 2032 With Action condition are expected to also address the potential transit impacts during construction. As with the 2028 and 2032 With Action conditions, the projected subway line-haul impact during the weekday AM peak period may remain unmitigated. ~~Additionally, as discussed in more detail in Chapter 14, "Transportation," and Chapter 21, "Mitigation," subway station impacts may remain unmitigated, if mitigation options are found to be infeasible, or if NYCT changes the current game day operation of the station.~~

Pedestrian trips during peak construction in 2031 would primarily be concentrated during off-peak hours (6 to 7 AM and 3 to 4 PM) and would be distributed among numerous pedestrian facilities in the area. Accordingly, there would also not be a potential for significant adverse pedestrian impacts attributable to the projected construction worker pedestrian trips. However, the significant adverse pedestrian impacts disclosed for the 2032 With Action condition may also occur during peak construction in 2031. Similar mitigation measures as those identified for the 2032 With Action condition are expected to also address the potential pedestrian impacts during construction. At locations where the proposed project is expected to result in unmitigated significant adverse pedestrian impacts, these impacts could similarly exist during construction.

AIR QUALITY

Based on a detailed analysis of construction during Phase 2 and a qualitative evaluation of construction during Phases 1A and 1B, the proposed project would not result in significant adverse impacts with respect to air quality. A detailed analysis of the combined effects of on-site and on-road emissions, determined that annual-average nitrogen dioxide (NO₂), carbon monoxide (CO), and particulate matter with an aerodynamic diameter less than 10 microns (PM₁₀) and particulate matter with an aerodynamic diameter less than 2.5 microns (PM_{2.5}) concentrations would be below their corresponding National Ambient Air Quality Standards (NAAQS) or de minimis criteria. Therefore, the proposed projects would not cause or contribute to any significant adverse air quality impacts with respect to these standards.

~~Dispersion modeling determined that the maximum predicted incremental concentrations of PM_{2.5} (using a worst case emissions scenario) would exceed the City's applicable 24-hour interim guidance criterion of 2 µg/m³ at a few receptor locations on the northeastern façade of parcel A1 during the construction activities at parcel A11 located immediately to the northeast, where the likelihood of prolonged exposure is very low.~~

~~The maximum predicted incremental concentrations of PM_{2.5} would also exceed 2 µg/m³ at a sidewalk location due to mobile sources on the southeast corner of 34th Avenue and 126th Street. The occurrences of elevated 24-hour average concentrations for PM_{2.5} would be limited in duration, frequency, and magnitude. Therefore, after taking into account the limited duration and extent of these predicted exceedances, and the limited area wide extent of the 24-hour impacts, it is concluded that no significant adverse air quality impacts for PM_{2.5} are expected from construction.~~

Because background concentrations are not known and the analysis methodology for mobile and construction sources have not been developed for the new 1-hour NO₂ NAAQS, exceedances of the 1-hour NO₂ standard resulting from construction activities cannot be ruled out. Therefore,

measures including diesel equipment reduction, utilization of newer equipment, and source location and idling restriction, would be implemented by the proposed project to minimize NO_x emissions from construction activities.

NOISE AND VIBRATION

Based on a detailed analysis of construction during Phase 2 and a qualitative evaluation of construction during Phases 1A and 1B, construction activities would not be expected to result in significant noise impacts at any nearby sensitive receptor locations. Proposed buildings that would be completed and occupied before construction is completed at other project building sites would also experience exterior noise levels due to construction activities in the low 70s to mid-80s dBA range. The design of all project buildings would include building façades providing not less than 31-43 dBA of attenuation and alternate means of ventilation (i.e., air conditioners) that do not degrade the acoustical performance of the façade. During the time period when these proposed buildings would be occupied and loud construction activities would be underway at immediately adjacent building sites (approximately two years according to the conceptual construction schedule on which the construction noise analysis is based), interior noise levels would, during some times, exceed 45 dBA L₁₀₍₁₎ (the CEQR acceptable interior noise level criteria for residential uses). Such exceedances may be intrusive, but would be only temporary and of limited duration. Consequently, they would not result in any significant impacts.

On-site, construction activities would produce L₁₀₍₁₎ noise levels at open space areas up to approximately the mid 70s dBA, which would exceed the levels recommended by CEQR for passive open spaces (55 dBA L₁₀). (Noise levels in these areas exceed CEQR recommended values for existing and No Action conditions.) While this is not desirable, there is no effective practical mitigation¹ that could be implemented to avoid these levels during construction. Noise levels in many parks and open space areas throughout the city, which are located near heavily trafficked roadways and/or near construction sites, experience comparable and sometimes higher noise levels, and consequently such levels would not be considered a significant adverse impact. Noise levels in many parks and open space areas throughout the city, which are located near heavily trafficked roadways and/or near construction sites, experience comparable and sometimes higher noise and consequently such levels would not be considered a significant adverse impact.

OTHER TECHNICAL AREAS

Consistent with the 2008 FGEIS and subsequent technical memoranda, and as described in greater detail below, construction of the proposed project would not be expected to result in any significant adverse impacts to land use, socioeconomic conditions, community facilities, open space, or natural resources.

Consistent with the findings in the 2008 FGEIS, construction activities related to the development that would occur within the Special Willets Point District during Phase 2 of the proposed project would be anticipated to result in the demolition of the former Empire Millwork Corporation Building, which was found by the New York State Office of Parks, Recreation, and Historic Preservation (OPRHP) to be eligible for listing on the State and National Registers of

¹ Noise barriers would not be practical because of security concerns.

Historic Places (S/NR). Demolition of this structure would be considered a significant adverse effect on this architectural resource.

As described in detail in Chapter 10, “Hazardous Materials,” and consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts related to hazardous materials during construction. To avoid the potential for significant adverse impacts related to hazardous materials, the proposed project would include appropriate health and safety (e.g., dust control and air monitoring) and investigative/remedial (e.g., delineating and excavating contaminated soils and disposing of them off site at an appropriately licensed facility) measures that would precede or govern both demolition and soil disturbance activities. These measures would be conducted in compliance with all applicable laws and regulations and would conform to appropriate engineering practices.

Construction would create major direct benefits resulting from expenditures on labor, materials, and services, and indirect benefits created by expenditures by material suppliers, construction workers, and other employees involved in the direct activity.

MITIGATION

COMMUNITY FACILITIES AND SERVICES

As described in Chapter 4, “Community Facilities and Services,” the lead agency, in consultation with the Queens Public Library, has determined that the additional population introduced by the proposed project would impair the delivery of library services in the study area in 2032. Therefore, Phase 2 of the proposed project would result in a significant adverse impact on library services. To mitigate this impact, adequate space¹ within the 125,000 square feet of as-yet-unprogrammed community facility space in the program for Phase 2 ~~could potentially~~ would be made available to be utilized as a branch library or auxiliary facility for the Queens Library system, or additional volumes or programs to accommodate new users could be provided if adequate space in nearby branches exists. Although no developer has yet been designated for Phase 2, the provision of additional library space in Phase 2 would be based on further consultation with Queens Public Library and the lead agency.

As discussed in Chapter 4, “Community Facilities and Services,” the analysis of indirect effects on child care facilities finds that the proposed project may result in significant adverse impacts on publicly funded child care facilities in 2028. Therefore, consistent with the conclusions of the 2008 FGEIS, to mitigate the potential impact on child care facilities that could occur by 2028, the QDG (i) would consult with ACS to determine whether adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site is the appropriate way to meet demand for child care services generated by the proposed project; and (ii) would, as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site. To mitigate the potential impact on child care facilities that could occur by 2032, EDC would require, as part of the developer’s agreement, that the designated developer of Phase 2 similarly consult with ACS to determine the appropriate way to meet demand for child care services generated by development in the District

¹ In other projects, 15,000–20,000 square feet of community facility space has been adequate for the operation of a branch library.

by 2032 and would, as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site.

~~Possible mitigation measures, which would be implemented by the developer(s) of Phase 1B and Phase 2, include adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site. At this point, however, it is not possible to know exactly which type of mitigation would be most appropriate and when, because several factors may limit the number of children in need of publicly funded child care slots. Families in the study area could make use of alternatives to publicly funded child care facilities, such as homes licensed to provide family child care which families of eligible children could elect to use instead of a public child care center. In addition, parents of eligible children may use ACS vouchers to finance care at private child care centers either within the study area or could use facilities outside of study area.~~

HISTORIC AND CULTURAL RESOURCES

As discussed in Chapter 7, “Historic and Cultural Resources,” there are substantial challenges inherent in retaining the historic building located in the District—the Former Empire Millwork Corporation Building—and the proposed project contemplates demolition of this building in Phase 2. A developer for Phase 2 has not yet been selected, and QDG may or may not be selected as the designated developer for Phase 2. Before the development of Phase 2, the selected developer will consult with the New York State Office of Parks, Recreation and Historic Preservation (OPRHP) and the New York City Landmarks Preservation Commission (LPC) to evaluate any remaining potential alternatives to demolition. If none are identified, measures to mitigate this adverse impact would be developed in consultation with OPRHP and LPC. The mitigation measures could include recording the building through a Historic American Buildings Survey (HABS)-level photographic documentation and accompanying narrative.

TRAFFIC AND PARKING

A broad range of traffic improvement measures would be needed to mitigate projected significant adverse traffic impacts. Intersection traffic improvements ~~will require~~ have received approval from the New York City Department of Transportation (NYCDOT). Overall, these intersection traffic improvements—including signal phasing and timing changes, traffic signal installations, lane additions, lane re-striping, geometric improvements, turn prohibitions, channelization improvements and parking prohibitions—fall within the range of typical measures employed by NYCDOT in improving traffic conditions in New York City. Each of the highway network-related improvements beyond the operational improvements which are under NYCDOT jurisdiction would require a collaborative review process between NYCDOT and the New York State Department of Transportation (NYSDOT), and where appropriate, DPR closer to the time of construction when the design of those measures is finalized.

The analyses have not identified significant parking impacts requiring mitigation in its various Build phases. However, the implementation of the traffic mitigation measures would result in the removal of parking or “standing” spaces during various times of the day and days of the week: approximately ~~60~~ 66 such spaces during Phase 1A; ~~94~~ 87 spaces during Phase 1B; ~~94~~ 101 spaces during Phase 2. No designated truck loading/unloading or commercial vehicle zones or bus layover space would be affected.

New traffic signals are proposed at the following, currently unsignalized, intersections: Boat Basin Road at World’s Fair Marina; the intersection of the Grand Central Parkway westbound

Willets Point Development

exit ramp at West Park Loop/Stadium Road; Willets Point Boulevard at Northern Boulevard; New Willets Point Boulevard at 126th Street; ~~and the intersection of the eastbound Northern Boulevard ramp to 126th Street at the eastbound Astoria Boulevard/Grand Central Parkway ramp to eastbound Northern Boulevard; Northern Boulevard at 126th Place; 126th Street at 36th Avenue; and 126th Street at 37th Avenue.~~ An upgrade to an actuated signal control at the intersection of Boat Basin Road at Stadium Road and traffic signal equipment upgrades from the current mechanical systems to computerized systems at the intersection of College Point Boulevard and Sanford Avenue are proposed in order to accommodate variable signal phase green times among the seven analysis time periods. ~~Should NYCDOT determine that any of the proposed traffic signals are not warranted, alternative means of mitigating significant adverse impacts at those locations will need to be developed or unmitigated impacts may result and would be identified as such in the Final SEIS.~~

In order to verify the need and effectiveness of the mitigation measures proposed in this SEIS (especially the more cost intensive highway network improvements), the developer, in consultation with the lead agency and NYCDOT, will develop and conduct a detailed traffic monitoring plan at the completion of the buildout phases of the proposed project. The traffic monitoring plan is described further in Chapter 21, "Mitigation." The developer will submit to NYCDOT and the lead agency design drawings for any mitigation measures as per American Association of State Highway and Transportation Officials (AASHTO) and NYCDOT specifications. NYCDOT will participate in the review process relating to all future modifications to geometric alignment, striping, and signage during the preliminary and final design phases. In addition, as mutually agreed upon, the City and the developer will be responsible for any cost associated with the monitoring effort. The developer of each phase of the project will be responsible for the cost of the design and construction of any or all mitigation measures identified in this SEIS, for that phase.

Depending on the peak traffic hour analyzed, approximately one-half or more of the significantly impacted intersections could be fully or partially mitigated with traffic signal phasing or timing changes, signalization of unsignalized intersections, lane re-striping, parking prohibitions, or turn prohibitions. Three locations at or near highway exit ramps would require more intensive mitigation measures such as roadway widenings and reconfigurations that have been incorporated in the traffic mitigation analyses. These measures would collectively improve conditions but would not be able to fully mitigate all projected impacts. Final design for construction of those measures which do not fall under the jurisdiction of NYCDOT will be further reviewed by NYSDOT closer to the time of construction. If these mitigation measures are modified or rejected by NYSDOT, significant adverse impacts identified above may be unmitigated.

Under Phase 1A, the number of unmitigated or partially mitigated intersections would range from a low of ~~two~~ three in the weekday AM peak hour on non-game days to a high of ~~six~~ ten under weeknight pre-game and weekend post-game conditions. Under Phase 1B, the number of unmitigated or partially mitigated intersections would range from a low of ~~four~~ five in the weekday AM peak hour on non-game days to a high of 12 under weekday PM and Saturday midday conditions on non-game days and all three game day peak hours. Under Phase 2, the number of unmitigated or partially mitigated intersections would range from a low of ~~eight~~ ten in the weekday AM peak hour on non-game days to a high of ~~15~~ 16 under weekday and Saturday midday conditions on non-game days and Saturday post-game conditions. ~~In addition, the~~

~~intersections of 126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place are expected to carry a significant amount of project generated trips in all three project phases. These three intersections were not analyzed for this Draft SEIS since the majority of project generated trips from the District were assigned to the adjacent analyzed intersections. Since impacts have been identified for these adjacent intersections, the three intersections listed above will be analyzed for the Final SEIS to determine if they would similarly experience significant adverse impacts. If they are found to be significantly impacted under the With Action condition, mitigation measures would be explored to address the impacts, or if no practicable mitigation measures can be identified, the impacts would be disclosed as being unmitigatable.~~

Improvements to local intersections and highway ramps would also mitigate some, but not all, significant highway impacts if implemented. Highway network improvements were not identified as mitigation in the 2008 FGEIS analyses. Both this SEIS and the 2008 FGEIS, however, include the new Van Wyck Expressway ramps as part of the With Action (i.e., Build) analyses in its expected implementation year. ~~Additional evaluations may be needed for the Final SEIS and could identify alternative measures that are deemed preferable to those identified in the Draft SEIS, in which case additional analyses may determine that projected conditions are better than those depicted in the Draft SEIS, or which may identify some deterioration in conditions and potential for previously identified significant adverse impacts that would be unmitigated or partially mitigated.~~

TRANSIT AND PEDESTRIANS

The proposed project would not result in any significant adverse transit impacts by the 2018 Phase 1A completion. However, it would result in significant adverse bus line-haul impacts on the Q19, Q48, and Q66 bus lines and subway line-haul impacts on the No. 7 Subway line by the 2028 Phase 1B completion. It should be noted that this significant adverse line-haul impact on the No. 7 line would not occur until Phase 2 should NYCT be able to process an additional Manhattan-bound express train during the AM peak hour, as assumed in the Draft SEIS. Upon the proposed project's full build-out in 2032, significant adverse transit impacts were identified for the Mets-Willets Point subway station stairs, the No. 7 subway line-haul, and Q19, Q48, and Q66 bus line-haul conditions. In addition, if NYCT reverts back to its pre-CitiField station operating plan for the Mets-Willets Point subway station, which would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day management strategies. However, additional impacts for the station's street-level connections and the unpaid zone passageway could occur during game days with this reconfiguration. Between the Draft and Final SEIS, no changes to operating plans were announced by NYCT; therefore, any potential changes that may be considered for future implementation will be addressed outside of this environmental review. For purposes of disclosure in this Final SEIS, any impacts that may be attributed to future passage of a reconfigured Mets-Willets Point subway station may potentially be deemed unmitigatable. For pedestrian operations, significant adverse impacts were identified for numerous study area crosswalks during all three analysis years.

To mitigate the 2032 significant adverse stairway impacts, the effective widths of the S-3, S-2, and M-4 stairways would need to be widened. In addition, these stairway widenings would need to be accompanied by an ADA-compliant elevator between the street and mezzanine levels. The feasibility of the stairway widening and elevator installation were ~~will be~~ further evaluated between the Draft and Final SEIS. ~~In the event these mitigation measures are determined to be infeasible, the~~

Willets Point Development

~~projected significant adverse stairway impacts would be deemed unmitigatable. Specifically, an engineering feasibility study and design schematics were prepared and concluded that the recommended stairway widenings, as well as the installation of an ADA-compliant elevator, would be feasible. It should be noted that the above proposed mitigation measures may be subject to modification due to NYCT's future master plan for the Mets-Willets Point subway station. Any modifications in conformance with the future master plan would provide equivalent functionalities that would similarly mitigate the stairway impacts identified above. Since the projected impacts that prompted the stairway and elevator feasibility study would not occur until Phase 2 of the proposed project, no funding commitments are in place at this time. The City will coordinate with NYCT and the lead agency to ensure the proper mitigation would be implemented at the appropriate time and would add language to the RFP for Phase 2 of the project as well as to the development agreement and/or other legally binding agreements, requiring the designated developer to fund the implementation of this mitigation. Since there are constraints on what service improvements are available to NYCT, the identified significant line-haul capacity impact on the No. 7 line would likely remain unmitigated absent the introduction of new LIRR service to the area. The addition of regular LIRR service to Willets Point would provide substantial relief to the No. 7 subway line and may prevent this significant adverse subway impact from materializing. To address the Q19, Q48, and Q66 bus line-haul impacts under Phases 1B and 2 in 2028 and 2032, respectively, substantial service improvements in terms of frequency of service would be required to meet the projected demand. Recognizing that these improvements may not be operationally viable or adequate in accommodating the projected future demand from developments planned for the District, discussions were initiated with NYCT to explore opportunities to extend existing bus routes from adjacent neighborhoods (e.g., downtown Flushing) and/or creating new bus routes. To accommodate these potential service improvements, new bus stops and layover areas would be needed in and around Willets West and the District. Between the Draft and Final SEIS, additional discussions were initiated with MTA NYCT regarding the potential bus service improvements discussed above. MTA NYCT considered the Q19 westbound loop to serve Willets West and the District to be unfavorable due to its circuitous routing. The MTA Bus Company would consider extending the Q50 and NYCT would consider extending one of the current bus routes terminating in downtown Flushing to Willets West and the District initially. Additional bus route extensions to Willets West and the District would be considered based on future demand. In addition, several conceptual bus routing options were explored to provide the necessary layover areas and stop locations for the potential bus route extensions. MTA NYCT has found the conceptual bus routing options to be generally reasonable and feasible. While no definitive plans have been made at this time, the City and applicant will continue to collaborate with MTA and NYCT during and after this environmental review process to ensure that adequate bus service improvements would be implemented.~~

To address the significant adverse pedestrian impacts, crosswalk widenings were proposed either solely or in conjunction with the proposed traffic mitigation measures. In some cases, achieving the widening necessary to mitigate the projected significant adverse impacts may not be feasible. Hence, these crosswalk impacts would be either partially mitigated or unmitigated. In addition, related pedestrian analyses ~~will be~~ were prepared for the three intersections (126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place) where additional traffic analyses ~~will were~~ also be conducted and ~~are presented in the this~~ Final EIS. Mitigation measures were recommended where appropriate for the additional three intersections. If additional pedestrian impacts are identified, mitigation measures would be explored to address

~~the impacts, or if no practicable mitigation measures can be identified, the impacts would be disclosed as being unmitigatable.~~

It should be noted that pedestrian volumes at some of the impacted crosswalks could be substantially lower if an areawide bus service improvement is implemented, as discussed above. As a result, some of the projected significant adverse pedestrian impacts may not occur or may occur to a lesser extent, requiring no or less mitigation. The reduction of pedestrian volumes at these crosswalk locations could also lessen pedestrian conflicts with turning vehicles, thereby potentially lessening the projected traffic impacts and required traffic mitigation measures. Similar to the proposed traffic mitigation measures, the eventual implementation of the proposed pedestrian mitigation measures would be subject to a monitoring program undertaken by the developer, in consultation with the lead agency and NYCDOT, to determine actual needs upon completion and occupancy of various components during the three phases of the proposed project.

AIR QUALITY

The proposed project would not result in significant adverse impacts on air quality. Therefore, no air quality mitigation is required. Since the proposed traffic mitigation measures would alter traffic conditions when compared with the proposed project, the localized air quality impacts with mitigation were modeled. With traffic mitigation measures, the predicted 8-hour average carbon dioxide concentration increments from mobile sources were predicted to be below the CO *de minimis* concentration, and the PM₁₀ 24-hour concentrations when added to the background PM₁₀ levels were predicted to be less than the National Ambient Air Quality Standard. PM_{2.5} 24-hour average and annual average concentration increments with the traffic mitigation measures would not exceed the PM_{2.5} *de minimis* criteria. Therefore, no significant adverse air quality impacts would occur as a result of the proposed traffic mitigation measures. ~~above 2 µg/m³ were predicted. Based on the magnitude, extent, and frequency of 24-hour average PM_{2.5} concentrations above 2.0 µg/m³, the proposed project with traffic mitigation would not result in significant PM_{2.5} impacts. Furthermore, the maximum predicted 24-hour average concentrations with traffic mitigation when added to the PM_{2.5} background concentration of 26 µg/m³ would be less than the corresponding NAAQS of 35 µg/m³.~~

NOISE

The proposed project would not result in any significant adverse noise impacts. Therefore, no noise mitigation measures are required. Since the proposed traffic mitigation measures would alter traffic conditions when compared with the proposed project, noise levels at sensitive receptor locations with the traffic mitigation measures in effect were examined. The analysis of noise levels with the proposed traffic mitigation measures found that noise levels would increase less than 1 dBA with the proposed traffic mitigation measures, which would be considered imperceptible and insignificant according to CEQR criteria.

ALTERNATIVES

NO ACTION ALTERNATIVE

The No Action Alternative assumes the continuation of existing uses on the various portions of the project site. Since this alternative would allow the continued industrial use of the District, it would not allow for development of affordable housing, community facilities, schools, and

public open space. It also would not comprehensively remediate contaminated soils and groundwater, nor provide new sanitary and storm sewers; as a result, there would continue to be degraded water quality and potential impacts to aquatic biota through the continued discharge of wastewater, polluted stormwater, and sediments from the District to the Flushing River, Flushing Bay, and groundwater aquifers. Because the No Action Alternative would not develop new retail and entertainment uses at Willets West and the District, it would not generate the substantial economic and civic benefits resulting from the proposed project in the way of new jobs and tax revenues. Moreover, this alternative would not advance a number of the Downtown Flushing Development Framework's fundamental goals, including the creation of a regional destination that would enhance economic growth in Downtown Flushing and Corona, improvement of environmental conditions, and integration of new development in the District with surrounding amenities. The former Empire Millwork Corporation Building would remain under private ownership in the No Action Alternative and could be demolished as-of-right; mitigation measures such as photographic documentation would not be required.

NO UNMITIGATED SIGNIFICANT IMPACTS ALTERNATIVE

The No Unmitigated Significant Impacts Alternative explores modifications to the proposed project that would avoid the unmitigated significant impacts to historic and cultural resources, traffic, transit, and pedestrians:

- For historic and cultural resources, this alternative would avoid the demolition of the former Empire Millwork Corporation Building that would occur with Phase 2 of the proposed project. Although this could be achieved through adaptive reuse, exterior elements would still need to be upgraded to comply with building codes and noise attenuation requirements, and flood protection measures such as gates or pumps would be required to comply with flood insurance requirements. Overall, this alternative would reduce the footprint of any new development, which would result in greater density in the remainder of the District, fewer housing units, less open space, or some combination of these possibilities. As noted above, the former Empire Millwork Corporation Building could be demolished as-of-right under existing conditions, and mitigation measures such as photographic documentation would not be required.
- For traffic, the proposed project and the potential future development on Lot B would result in significant adverse impacts that cannot be fully alleviated with practical mitigation measures. Because of existing congestion at a number of intersections, even a minimal increase in traffic would result in unmitigated impacts. Based on a sensitivity analysis of intersections within the study area, it was determined that in all three phases of the proposed project, the addition of five or fewer vehicles through some intersections would trigger an impact that cannot be fully mitigated. Thus, almost any new development at the project site would result in unmitigated traffic impacts, and no reasonable alternative could be developed to avoid such impacts.
- For transit, the proposed project and potential future development on Lot B would result in significant adverse subway line-haul impacts on the Manhattan-bound No.7 subway line express service during the 2028 and 2032 AM peak periods and on station operations at the Mets-Willets Point subway station under the 2018, 2028, and 2032 With Action conditions. Should NYCT revert back to its pre-CitiField station operating plan for the Mets-Willets Point subway station, the significant adverse impacts on station operations may potentially be deemed unmitigatable. Although the City had consulted with the MTA on extending

- regular LIRR service to Willets Point, which would be expected to provide substantial relief to the No. 7 subway line and may prevent this significant adverse subway impact from materializing, the implementation of the LIRR service improvement would depend on whether the actual future demand shows that such service improvement is warranted. It should be noted that this significant adverse line-haul impact on the No. 7 line would not occur until Phase 2 should NYCT be able to process an additional Manhattan-bound express train during the AM peak hour, as assumed in the Draft SEIS. To avoid this potentially unmitigatable impact, portions or all of Phase 1B and Phase 2 of the proposed project and the potential future development on Lot B would need to be eliminated from the current development plan. Almost any new development at the project site would result in the potentially unmitigatable impact on station operations at the Mets-Willets Point subway station, and no reasonable alternative could be developed to avoid such impacts without substantially compromising the proposed project's stated goals.
- For pedestrians, the proposed project and potential future development on Lot B would result in significant adverse impacts at ~~five~~ seven study area crosswalks upon Phase 1A completion in 2018, five study area crosswalks upon and Phase 1B completion in 2028, and seven study area crosswalks upon the Phase 2 full-build out in 2032. ~~2018 and 2028, respectively, and at eight study area crosswalks upon the Phase 2 full build out in 2032.~~ No reasonable alternative could be developed to avoid these impacts without substantially compromising the proposed project's stated goals.

UNAVOIDABLE ADVERSE IMPACTS

INTRODUCTION

Unavoidable significant adverse impacts are defined as those for which there are no reasonably practicable mitigation measures to eliminate the impacts; and there are no reasonable alternatives to the proposed project that would meet the purpose and need of the action, eliminate the impact, and not cause other or similar significant adverse impacts.

As described in "Mitigation," a number of the potential impacts identified for the proposed project could be mitigated. However, as described below, in some cases, project impacts would not be fully mitigated.

HISTORIC AND CULTURAL RESOURCES

Phase 2 of the proposed project contemplates demolition of the former Empire Millwork Corporation Building, located at 128-50 Willets Point Boulevard in the Special Willets Point District. Demolition of this building would constitute a significant adverse impact on this historic resource. A developer for Phase 2 has not yet been selected, and QDG may or may not be selected as the designated developer for Phase 2. Before the development of Phase 2, the selected developer will consult with OPRHP and LPC to evaluate any remaining potential alternatives to demolition. If none are identified, measures to mitigate this adverse impact would be developed in consultation with OPRHP and LPC. The mitigation measures could include recording the building through a HABS-level photographic documentation and accompanying narrative. However, this impact would not be completely eliminated, as the resource would still be demolished. Therefore, consistent with the conclusions of the 2008 FGEIS, the demolition would constitute an unavoidable significant adverse impact on this historic resource as a result of the proposed project.

TRANSPORTATION

Traffic and Parking

The proposed project would result in unmitigated impacts at local intersections and highway elements within the traffic study area and partially mitigated impacts at other locations. Not all of the unmitigated impact locations would occur in all seven traffic analysis periods. This section summarizes the unmitigated and partially mitigated locations based on the mitigation measures described in “Mitigation.”

Local Intersections

Under Phase 1A, ~~8~~ 13 of the ~~29~~ 32 intersections analyzed would have significant impacts that could not be fully mitigated in at least one peak hour, including:

- Astoria Boulevard at 108th Street;
- Northern Boulevard at 126th Street, Prince Street and at Main Street;
- Roosevelt Avenue at 108th Street, 114th Street, 126th Street, College Point Boulevard, and Union Street; ~~and~~
- 126th Street at 34th Avenue, 36th Avenue, and 37th Avenue; and
- Boat Basin Road at Stadium Road.

Under Phase 1B, ~~44~~ 18 of the ~~30~~ 33 intersections analyzed (there is one additional intersection analyzed in the study area under Phase 1B) would have significant impacts that could not be fully mitigated in at least one peak hour, including the following locations in addition to those cited above for Phase 1A (Note: the intersection of Roosevelt Avenue at 108th Street, which could not be fully mitigated in Phase 1A, could be fully mitigated in Phase 1B):

- Northern Boulevard at Union Street and at Parsons Boulevard;
- ~~34th Avenue at 126th Street;~~
- Roosevelt Avenue at 111th Street, at Main Street, and at Parsons Boulevard; and
- Sanford Avenue at Parsons Boulevard.

Under Phase 2, ~~48~~ 23 of the ~~34~~ 34 intersections analyzed (there is one more intersection analyzed in the study area under Phase 2) would have significant impacts that could not be fully mitigated in at least one peak hour, including the following locations in addition to those cited above for Phase 1B:

- Northern Boulevard at 108th Street and at 114th Street;
- Roosevelt Avenue at ~~114th~~ 108th Street and Prince Street; and
- Northern Boulevard at College Point Boulevard.

Highway Network

Under Phase 1A, 6 of the 19 highway elements analyzed would have significant impacts that could not be fully mitigated in at least one peak hour, including:

- Westbound Grand Central Parkway (GCP) mainline (east side and west side), between Roosevelt Avenue and the Long Island Expressway (LIE);
- ~~Southbound Whitestone Expressway mainline between Northern Boulevard and Linden Place; Southbound Van Wyck Expressway between Roosevelt Avenue and LIE;~~

- Ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway;
- Ramp from the Grand Central Parkway/eastbound Astoria Boulevard to the northbound Whitestone Expressway/eastbound Northern Boulevard; and
- Ramp from the southbound Whitestone Expressway to westbound Northern Boulevard.

~~There would be additional highway locations that would be slightly or moderately impacted due to the implementation of mitigation measures at local intersections and highway ramps. In Phase 1A, the eastbound GCP mainline between Roosevelt Avenue and the LIE would be slightly impacted and unmitigated during one of the seven peak traffic analysis hours.~~

Under Phase 1B, ~~40~~ 11 of the 19 analyzed highway elements would have significant traffic impacts that could not be fully mitigated in at least one peak hour, including the following locations in addition to those cited under Phase 1A (Note: the ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway, which could not be fully mitigated in Phase 1A, could be fully mitigated in Phase 1B):

- Northbound Van Wyck Expressway mainline between Roosevelt Avenue and the LIE;
- Southbound Whitestone Expressway mainline between Northern Boulevard and Linden Place;
- Ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard;
- Ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard;
- Ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway; and
- Ramp from the westbound GCP toward Stadium Road and the northbound Whitestone Expressway.

~~As mentioned above for Phase 1A, In Phase 1B there would be additional highway locations that would be slightly or moderately impacted due to the implementation of mitigation measures at local intersections and highway ramps, including the following in addition to the one location cited above for Phase 1A:~~

- Eastbound Grand Central Parkway mainline between Roosevelt Avenue and the LIE;
- Southbound Van Wyck Expressway mainline between Roosevelt Avenue and the LIE;
- Southbound Whitestone Expressway mainline between Northern Boulevard and Linden Place; and
- Ramp from World's Fair Marina/Boat Basin Road to the westbound Grand Central Parkway.
- ~~Ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway; and~~
- ~~Ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway.~~

Under Phase 2, the same ~~11~~ 11 of the 19 analyzed highway elements would have significant impacts that could not be fully mitigated in at least one peak hour as in Phases 1A and 1B above. ~~, including the following location in addition to those cited for Phases 1A and 1B:~~

- ~~Southbound Van Wyck Expressway mainline between Roosevelt Avenue and the LIE.~~

As mentioned above for Phases 1A and 1B, in Phase 2 there would be additional highway locations that would be slightly or moderately impacted due to the implementation of mitigation

Willets Point Development

measures at local intersections and highway ramps, including the following in addition to locations cited above for Phases 1A and 1B:

- Westbound Grand Central Parkway mainline (east side), between Roosevelt Avenue and the LIE;
- Northbound Whitestone Expressway mainline between Northern Boulevard and Linden Place;
- Ramp from World's Fair Marina/Boat Basin Road to the westbound GCP; and
- Ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway;
- Ramp from the southbound Whitestone Expressway to the westbound GCP; and
- Ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway.

~~Some intensive mitigation measures would be required to partially or fully mitigate significant impacts at several locations. If these measures are not implemented, and equivalent mitigation measures are not identified, the number or severity of unmitigated impacts would increase.~~

TRANSIT AND PEDESTRIANS

The proposed project would potentially result in unmitigated significant adverse impacts on station operations at the Mets-Willets Point subway station under the 2018, 2028, and 2032 With Action conditions, subway line haul operations for the No. 7 line under the 2032 With Action condition, and street level pedestrian facility operations under the 2018, 2028, and 2032 With Action conditions. Not all of these potentially unmitigated impacts would occur in all analysis time periods. This section summarizes the potentially unmitigated and partially mitigated locations; for additional information, see "Mitigation."

Subway Station Operations

Under Phase 2, the proposed project would result in significant adverse impacts on the S-3, S-2, and M-4 stairways located on the north side of Roosevelt Avenue, requiring stairway widenings and the installation of an ADA-compliant elevator between the street and mezzanine levels. The feasibility of the stairway widening and elevator installation ~~were~~ will be further evaluated between the Draft and Final SEIS. ~~In the event these mitigation measures are determined to be infeasible, the projected significant adverse stairway impacts would be deemed unmitigatable. Specifically, an engineering feasibility study and design schematics were prepared and concluded that the recommended stairway widenings, as well as the installation of an ADA-compliant elevator, would be feasible. It should be noted that the above proposed mitigation measures may be subject to modification due to NYCT's future master plan for the Mets-Willets Point subway station. Any modifications in conformance with the future master plan would provide equivalent functionalities that would similarly mitigate the stairway impacts identified above. Since the projected impacts that prompted the stairway and elevator feasibility study would not occur until Phase 2 of the proposed project, no funding commitments are in place at this time. The City will coordinate with NYCT and the lead agency to ensure the proper mitigation would be implemented at the appropriate time and would add language to the RFP for Phase 2 of the project as well as to the development agreement and/or other legally binding agreements, requiring the designated developer to fund the implementation of this mitigation.~~

In addition, NYCT may revert back to its pre-CitiField station operating plan for the Mets-Willets Point subway station, whereby passage through the station between parking in South

Lot/Lot D and the north side of Roosevelt Avenue could be made only within the unpaid zone. If NYCT decides to proceed with this plan, which would take place independent of the proposed project, additional impacts for the station's street-level connections and the unpaid zone passageway could occur during game days. Although these impacts would be intermittent, occurring on average only approximately 80 40 to 50 times a year, and subject to game-day traffic and pedestrian management, they may potentially be deemed unmitigatable. No changes to operating plans were announced by NYCT between the Draft and Final Supplemental Environmental Impact Statements; therefore, any potential changes that may be considered for future implementation will be addressed outside of this environmental review.

Subway Line Haul

Under Phase 1B and Phase 2, the proposed project would result in a significant adverse impact on the Manhattan-bound No. 7 subway line express service during the AM peak period. It should be noted that this significant adverse line-haul impact on the No. 7 line would not occur until Phase 2 should NYCT be able to process an additional Manhattan-bound express train during the AM peak hour, as assumed in the Draft SEIS. The addition of regular LIRR service to Willets Point would provide substantial relief to the No. 7 subway line and may prevent this significant adverse subway impact from materializing. Since there are constraints on what service improvements are available to NYCT, the identified significant line-haul capacity impact on the No. 7 line would likely remain unmitigated absent the introduction of new LIRR service to the area.

Pedestrians

Under Phases 1A and 1B, widening the east crosswalk of Northern Boulevard and 126th Street could fully mitigate the significant adverse impact during all peak periods. However, if the proposed widening was determined to be infeasible, the projected significant adverse impacts at this crosswalk would be either partially mitigated or unmitigated.

Under Phase 2, widening the east crosswalk of Northern Boulevard and 126th Street, the west crosswalk of Roosevelt Avenue and 126th Street, and the east crosswalk of 34th Avenue and 126th Street could fully mitigate the significant adverse impacts during all peak periods. However, if the proposed widenings were determined to be infeasible, the projected significant adverse impacts at these crosswalks would be either partially mitigated or unmitigated.

In addition, related pedestrian analyses ~~will be~~ were prepared for the three intersections (126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place) where additional traffic analyses ~~will be~~ were also be conducted and are presented in ~~the~~ this Final SEIS. Mitigation measures were recommended where appropriate for the additional three intersections and would not result in any additional unmitigatable impacts. ~~If additional pedestrian impacts are identified, mitigation measures would be explored to address the impacts, or if no practicable mitigation measures can be identified, the impacts would be disclosed as being unmitigatable.~~

GROWTH-INDUCING ASPECTS OF THE PROPOSED PROJECT

Growth-inducing aspects of the proposed project are “secondary” impacts from the project that could trigger additional development in areas outside of the project site that would not have occurred without the proposed project. The *CEQR Technical Manual* indicates that an analysis of the growth-inducing aspects of a proposed action is appropriate when an action either adds

Willets Point Development

substantial new land use, new residents, or new employment that could induce additional development of a similar kind or of support uses, such as retail establishments to serve new residential uses; and/or introduces or greatly expands infrastructure capacity.

While the uses proposed for Willets West and the Special Willets Point District would contribute to growth in the local Queens, City, and State economies, they would not be expected to induce notable growth outside of the project site and the anticipated development on Lot B. It is unlikely that the proposed project and potential future development on Lot B would alter land use patterns in surrounding neighborhoods. Given the recent trend to redevelop underutilized sites near the Flushing River waterfront, it is possible that the proposed project and new development on Lot B could encourage further redevelopment of some nearby underutilized sites along the Flushing River. However, given that such changes are already under way, potential development parcels are limited, and the project site is physically separated from surrounding neighborhoods by water bodies, roadways, and parkland, the ability of the proposed project to alter land use and economic patterns or induce substantial growth in the study area would be minimal.

Substantial infrastructure and roadway improvements would be provided as part of the proposed project. The infrastructure and roadway improvements included in the proposed project are intended to support the anticipated growth in the Willets West and District portions of the project site, as well as the potential future development of Lot B. The infrastructure in the study area is already well-developed such that improvements associated with the proposed project would not induce additional growth.

IRRETRIEVABLE AND IRREVERSIBLE COMMITMENT OF RESOURCES

There are a number of resources, both natural and built, that would be expended in the construction and operation of the proposed project. These resources include the building materials used in construction of the proposed project; energy in the form of gas and electricity consumed during construction and operation of the proposed project; and the human effort required to develop, construct, and operate various components of the proposed project. They are considered irretrievably committed because their reuse for some purpose other than the proposed project would be highly unlikely. The proposed project constitutes a commitment of the project site as a land resource, thereby rendering the land's use for other purposes infeasible. However, the transformation of surface parking lots and a largely underutilized site with substandard conditions and substantial environmental degradation into a lively, mixed-use, sustainable community and regional destination would be an improvement to the District and areas surrounding CitiField. *

A. INTRODUCTION

This Supplemental Environmental Impact Statement (SEIS) addresses proposed modifications to the previously approved Willets Point Development Plan for the approximately 61-acre Special Willets Point District in Queens, to include the proposed “Willets West” development on the surface parking lot west of the CitiField baseball stadium; the development of structured parking facilities on surface parking Lot D and South Lot along Roosevelt Avenue, adjacent to the stadium (see **Figure 1-1**); and changes to the phasing of the project. With these modifications, the project site would comprise approximately 108.9 acres and the proposed project could result in up to 10.34 million square feet of development. This SEIS also considers changes in background conditions, including federal approval of the Freeway Access Modification Report (AMR) for new vehicular connections from the Special Willets Point District to the Van Wyck Expressway.

A Final Generic Environmental Impact Statement (FGEIS) for the Willets Point Development Plan (the Plan) was issued in September 2008 by the Office of the Deputy Mayor for Economic Development (ODMED) as lead agency under the New York State Environmental Quality Review Act (SEQRA), its implementing regulations (6 NYCRR Part 617), and New York City Environmental Quality Review (CEQR). The approved project was for redevelopment of a largely underutilized site with substandard conditions and environmental degradation—into a lively, sustainable community and regional destination with approximately 8.94 million square feet of residential, retail, hotel, convention center, entertainment, commercial office, community facility, open space, and parking uses.

The proposed modifications to the previously approved Willets Point Development Plan require public review, including by the local Community Board and the Queens Borough President, and approvals by government agencies, including the Office of the Deputy Mayor for Economic Development, the New York City Planning Commission (CPC), and the City Council. Because it has been determined that the proposed project may result in new or greater significant adverse impacts than were disclosed in the 2008 FGEIS, it requires review and the preparation of an SEIS under CEQR.

B. PROJECT BACKGROUND

Since World War II, there have been numerous attempts to redevelop Willets Point, which became known over the years for its many auto repair businesses and junkyards. Since 2000, these planning efforts have accelerated. In 2001, the City’s Department of Housing Preservation and Development (HPD) design workshop explored potential redevelopment ideas and recommended land uses that would connect Willets Point with neighboring communities and complement nearby attractions and facilities. In 2002, the City created the Downtown Flushing Task Force, which outlined land use and economic goals for the redevelopment of Willets Point in its Downtown Flushing Development Framework. The Downtown Flushing Development

Project Site Map
Figure 1-1

Willets Point Development

Framework became the starting point for the City's creation of the Willets Point Development Plan, which was approved by the City Council in 2008. The numerous actions required for the Plan—which included the creation of a new special zoning district (the Special Willets Point District) and an urban renewal plan for the area—required review under SEQRA and CEQR.

An FGEIS for the Willets Point Development Plan was issued in September 2008 by ODMED as lead agency under SEQRA, its implementing regulations (6 NYCRR Part 617), and CEQR. The Willets Point Development Plan was approved by the City Council in 2008. The approved project was for redevelopment of a largely underutilized site with substandard conditions and environmental degradation—into a lively, sustainable community and regional destination with approximately 8.94 million square feet of residential, retail, hotel, convention center, entertainment, commercial office, community facility, open space, and parking uses. Subsequent technical memoranda assessed the potential effects of modifications to the proposed actions and were accepted by ODMED; SEQRA findings were issued on February 11, 2011.

Subsequent to the City Council's approval of the Willets Point Development Plan in 2008, the City revised and reissued a Request for Qualifications and Request for Proposals for the redevelopment of this area. The City has also undertaken several measures that support the goals of the Plan, including measures related to site acquisition, assistance for District workers, advancement of the proposed connections to the Van Wyck Expressway, and ongoing infrastructure work. In December 2011, the City also broke ground on the new sanitary and storm water mains that will provide new public sanitary sewer service to support the redevelopment of the District and adjacent areas and replace an inadequately sized storm water sewer and outfall to help alleviate chronic flooding that occurs in the District and adjacent areas. Adjacent to the Special Willets Point District, the new CitiField stadium opened in 2009, replacing the former Shea Stadium, and the area formerly occupied by Shea Stadium was converted to a surface parking lot.

In 2012, in response to a competitive Request for Proposal process, the Queens Development Group, LLC (QDG)—a joint venture between the Related Companies and Sterling Equities—was selected as the City's designated developer for Phases 1A and 1B of the Willets Point Development Plan.¹ QDG is proposing to include in its proposed development additional land beyond the boundaries of the Special Willets Point District in order to develop portions of the main CitiField stadium parking field ("Willets West") and CitiField parking fields south of Roosevelt Avenue. QDG is also proposing to develop interim parking uses on a portion of the land within the Special Willets Point District to accommodate the stadium's parking demand during the initial phase of the area's proposed redevelopment. The discretionary actions needed for the proposed modifications include a zoning text amendment and a special permit to allow surface parking and recreational uses within the Special Willets Point District and modification of the City's existing lease for the CitiField parking lot, as well as potential additional actions discussed below.

PRIOR ENVIRONMENTAL REVIEW

The 2008 FGEIS examined the potential for significant impacts resulting from the redevelopment of the project site in the impact categories of land use, zoning, and public policy; socioeconomic conditions; community facilities; open space; shadows; historic resources; urban

¹ Formerly Phase 1 in Technical Memorandum #4, with some adjustments to footprint.

design and visual resources; neighborhood character; natural resources; hazardous materials; waterfront revitalization program; infrastructure; solid waste and sanitation; energy; traffic and parking; transit and pedestrians; air quality; noise; construction impacts; and public health. The 2008 FGEIS found that no significant adverse environmental impacts would result from the proposed development Plan with respect to land use, zoning, and public policy; socioeconomic conditions; open space; shadows; urban design and visual resources; neighborhood character; natural resources; waterfront revitalization program; infrastructure; solid waste and sanitation; energy air quality; construction impacts; and public health. Potentially significant impacts were identified for publicly funded child care, historic resources, hazardous materials, traffic, transit and pedestrians, and noise.

Subsequent to the issuance of the 2008 FGEIS, CPC proposed several modifications to the Special Willets Point District zoning regulations. These modifications were described, and their potential for significant adverse environmental impacts examined, in a technical memorandum dated September 23, 2008 (Technical Memorandum #1), which found that there were no additional impacts due to the modifications that had not been disclosed in the 2008 FGEIS. CPC voted in favor of the Willets Point Development Plan with those modifications on September 24, 2008.

Following the CPC vote, new information became available related to: negotiated property acquisition by the City in the District; Phase II Environmental Site Investigations (ESIs) in the District; the amount of affordable housing to be provided in the District (an increase from 20 to 35 percent); and projected school and day care populations. This information was described, and its potential to result in significant adverse environmental impacts not previously identified was examined, in a technical memorandum dated November 12, 2008 (Technical Memorandum #2). That technical memorandum concluded that none of the newly available information would lead to significant adverse environmental impacts that had not been identified and addressed in the 2008 FGEIS. The City Council voted to approve the Willets Point Development Plan with the CPC modifications on November 13, 2008.

In 2009, the City considered the effect of the economic downturn on the Willets Point project. The City anticipated that economic conditions would make it challenging for developers to finance the acquisition and remediation of the entire Willets Point site at one time and prior to any development, as described in the 2008 FGEIS. In a technical memorandum dated November 23, 2009 (Technical Memorandum #3), an Adjusted Plan for Willets Point was analyzed similar to the Staged Acquisition Alternative analyzed in the FGEIS. In the Adjusted Plan, remediation and development of an initial portion of the District would have proceeded first, followed by remediation and development of the remaining portion of the District. The Adjusted Plan assumed the same overall development program at full build-out as the Staged Acquisition Alternative (with revisions described in the prior technical memoranda), but anticipated a smaller development footprint during the first years of development, with approximately 70 percent as much floor area in the initial phase compared with the Staged Acquisition Alternative.

In a technical memorandum dated February 10, 2011 (Technical Memorandum #4), the City considered an Updated Plan that was similar to the Adjusted Plan analyzed in the 2009 technical memorandum as well as to the Staged Acquisition Alternative analyzed in the 2008 FGEIS. Compared with both the Adjusted Plan and the Staged Acquisition Alternative, the Updated Plan anticipated a smaller development footprint and less overall development (approximately 1.345 million gross square feet or gsf) in the first phase; however, at full build-out the Updated Plan would have developed the District with the same gross floor area and mix of uses as the Approved Plan

(with subsequent revisions described in the prior technical memoranda) and would have had the same controls on floor area ratios set forth in the provisions of the Special District zoning text that had been approved by CPC and the City Council.

A substantial difference between the Approved Plan and the Updated Plan was the timing of property acquisition and construction phasing. Under the Approved Plan, the necessary remediation, grading, and infrastructure improvements would have taken place across the District at the beginning stages of construction; in comparison, with the Updated Plan (as with the Staged Acquisition Alternative and the Adjusted Plan), development activities would have proceeded incrementally, with the necessary remediation, grading, infrastructure improvements, and construction activities associated with the buildings in the southwestern portion of the District occurring first, and construction activities on the remainder of the District following. Whereas the Staged Acquisition Alternative and Adjusted Plan assumed the District's connections to the Van Wyck Expressway would be constructed before the end of the first phase of development, with the Updated Plan these connections would have been completed no later than after the end of the first phase of development and before the first building to be developed in the second phase of construction is completed. Some negotiated acquisition might also have occurred within the remainder of the District during the initial phase of development.

In March 2012, the New York State Department of Environmental Coordination (NYSDEC) approved a State Pollutant Discharge Elimination System (SPDES) Construction Dewatering and Discharge Permit for construction of the proposed new sanitary and storm water mains for the Willets Point area. As described above, these improvements are currently being constructed.

The new connection to the Van Wyck Expressway, which was assumed in the 2008 FGEIS and subsequent technical memoranda, was subject to federal approval of the Freeway AMR. A Finding of No Significant Impact was issued and the AMR was approved in April 2012; the City has committed to provide capital funds for its construction.

C. PROJECT DESCRIPTION

SITE DESCRIPTION

The project site is composed of three discrete areas roughly bounded by Shea Road and Northern Boulevard to the north, the Van Wyck Expressway to the east, Roosevelt Avenue and the Metropolitan Transportation Authority (MTA) Corona Rail Yard to the south, and Shea Road to the west (see **Figures 1-1** and **1-2**). The “Willets Point” portion of the project site (the Special Willets Point District) comprises approximately 61 acres, approximately 15.8 acres of which are within public street right-of-ways, approximately 0.6 acres of which are owned by the MTA, and the remainder of which is a mix of privately owned land and land owned by the City. The Willets Point area comprises 128 tax lots and one partial lot (Block 1833, Lot 1) located on 14 blocks. Since the FGEIS was completed in 2008, the City has acquired, or is in contract to purchase, 95 percent of the land area within the proposed Phase 1A/1B footprint (Assemblage Option 2) in the District, and has control of 4 lots in the remainder of the District.

The “Willets West” portion of the project site is mapped parkland that comprises an approximately 30.7-acre section of the surface parking field west of CitiField. This area comprises a portion of Block 1787, Lot 20. The “Roosevelt Avenue” portions of the project site comprise three CitiField-related surface parking lots (South Lot and Lots B and D) along Roosevelt Avenue south and southwest of CitiField. The Lot B parking lot, which comprises a portion of Block 1787, Lot 20, is

approximately 4.7 acres in size; the South Lot and Lot D parking lot, which comprise a portion of Block 2018, Lot 1500, are together approximately 12.1 acres in size. Lot D and South Lot are used for commuter parking and United States Tennis Association (USTA) National Tennis Center (NTC) events when baseball games are not in progress.

In total, the project site comprises approximately 108.9 acres.

GOALS AND OBJECTIVES

The proposed project is intended to remediate and transform the area surrounding CitiField, which is largely separated from adjoining neighborhoods by major highways, into a thriving new neighborhood and regional destination. The project would expand on the goals and objectives of the original (2008) Willets Point Development Plan. By providing development that spans both sides of the new CitiField, the proposed project would allow for a more comprehensive and continuous neighborhood linking Flushing and Corona. The environmental degradation of the Special Willets Point District would be remediated. The commercial components of the proposed project would provide jobs and create new retail, hotel and entertainment uses that would complement the adjacent sports venue and strengthen economic activity in the neighborhood, borough, and City. The substantial residential component (which includes affordable housing units) would accommodate a portion of the City's current and future housing needs. The new structures and open spaces are intended to create an active streetscape that includes retail uses as part of a diverse mixed-use program, enhancing the pedestrian experience.

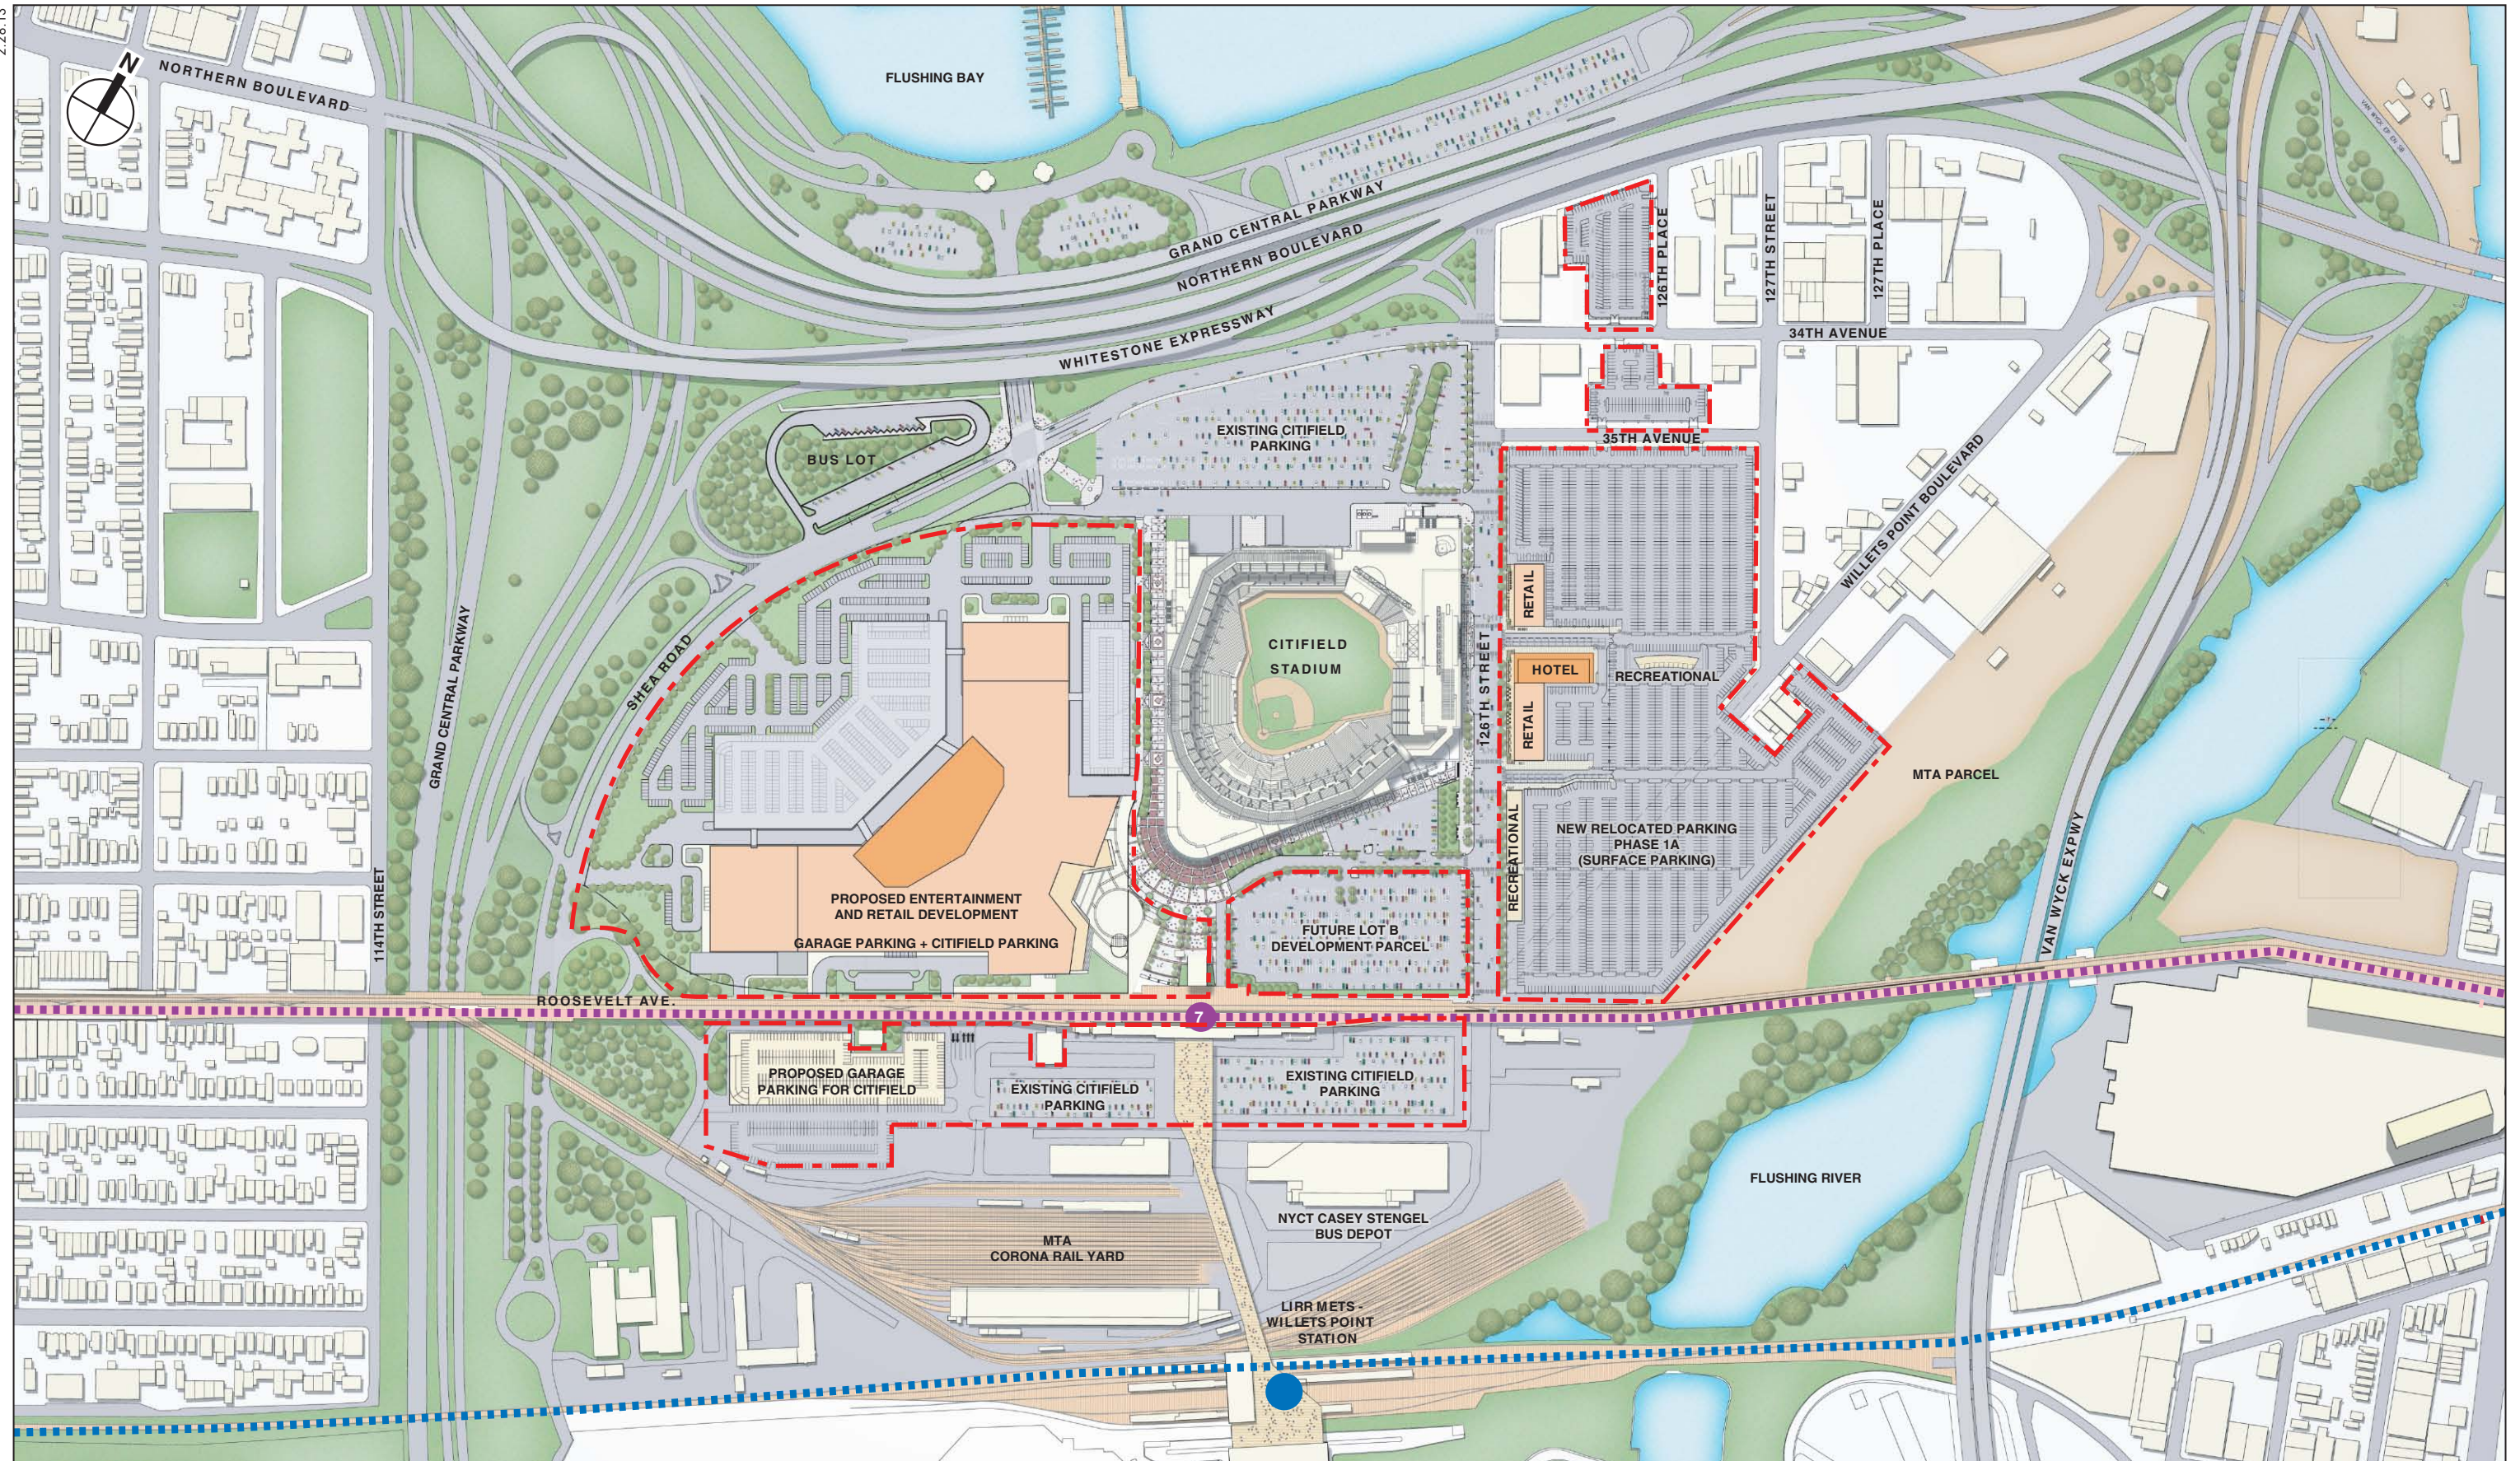

PROPOSED PROJECT

The proposed project would redevelop the Willets Point/CitiField area with a mix of uses that is expected to be completed by 2032. The redevelopment would incorporate a development in the Special Willets Point District substantially as anticipated and analyzed in the 2008 FGEIS and subsequent technical memoranda, as well as a major entertainment/retail component and parking adjacent to CitiField. Changes to the development analyzed here versus that analyzed in the 2008 FGEIS include an increase in the overall amount of retail development from 1.7 million square feet to 2.65 million square feet. This increase results from the 1.4 million gross square feet (1 million leasable square feet) of development at Willets West combined with a concurrent reduction in the overall amount of retail in the Special Willets Point District from 1.7 million square feet to 1.25 million square feet. The SEIS also assumes 5.85 million gross square feet of residential development to match the highest amount of residential analyzed in the 2008 FGEIS (in the No Convention Center Scenario), and a 230,000-square-foot school rather than the 2008 FGEIS's 130,000-square-foot school to accommodate a greater amount of the project's potential school seat demand.

The project is anticipated to proceed in three continuous phases, as follows.

PHASE 1A

The first phase of the project would commence with the remediation and development of an approximately 23-acre portion of the Special Willets Point District and the development of "Willets West" on the existing parking lot west of CitiField (see **Figures 1-3a** and **1-3b**). The 23-acre portion of the District would be remediated to address any hazardous materials issues. Upon completion of the environmental remediation, a 200-room hotel and associated parking, and approximately 30,000 square feet of retail space would be constructed above the floodplain along the east side of 126th Street, activating the 126th Street corridor—according to the District's regulations—with a 20-foot-

Willets Point Development

wide public esplanade, and a 2,750-space surface parking area would be developed east of the retail and hotel uses. The parking area would be converted to active recreational use a minimum of 6 months per year. This interim parking/recreational area would be replaced by permanent development in Phase 1B, as described below.

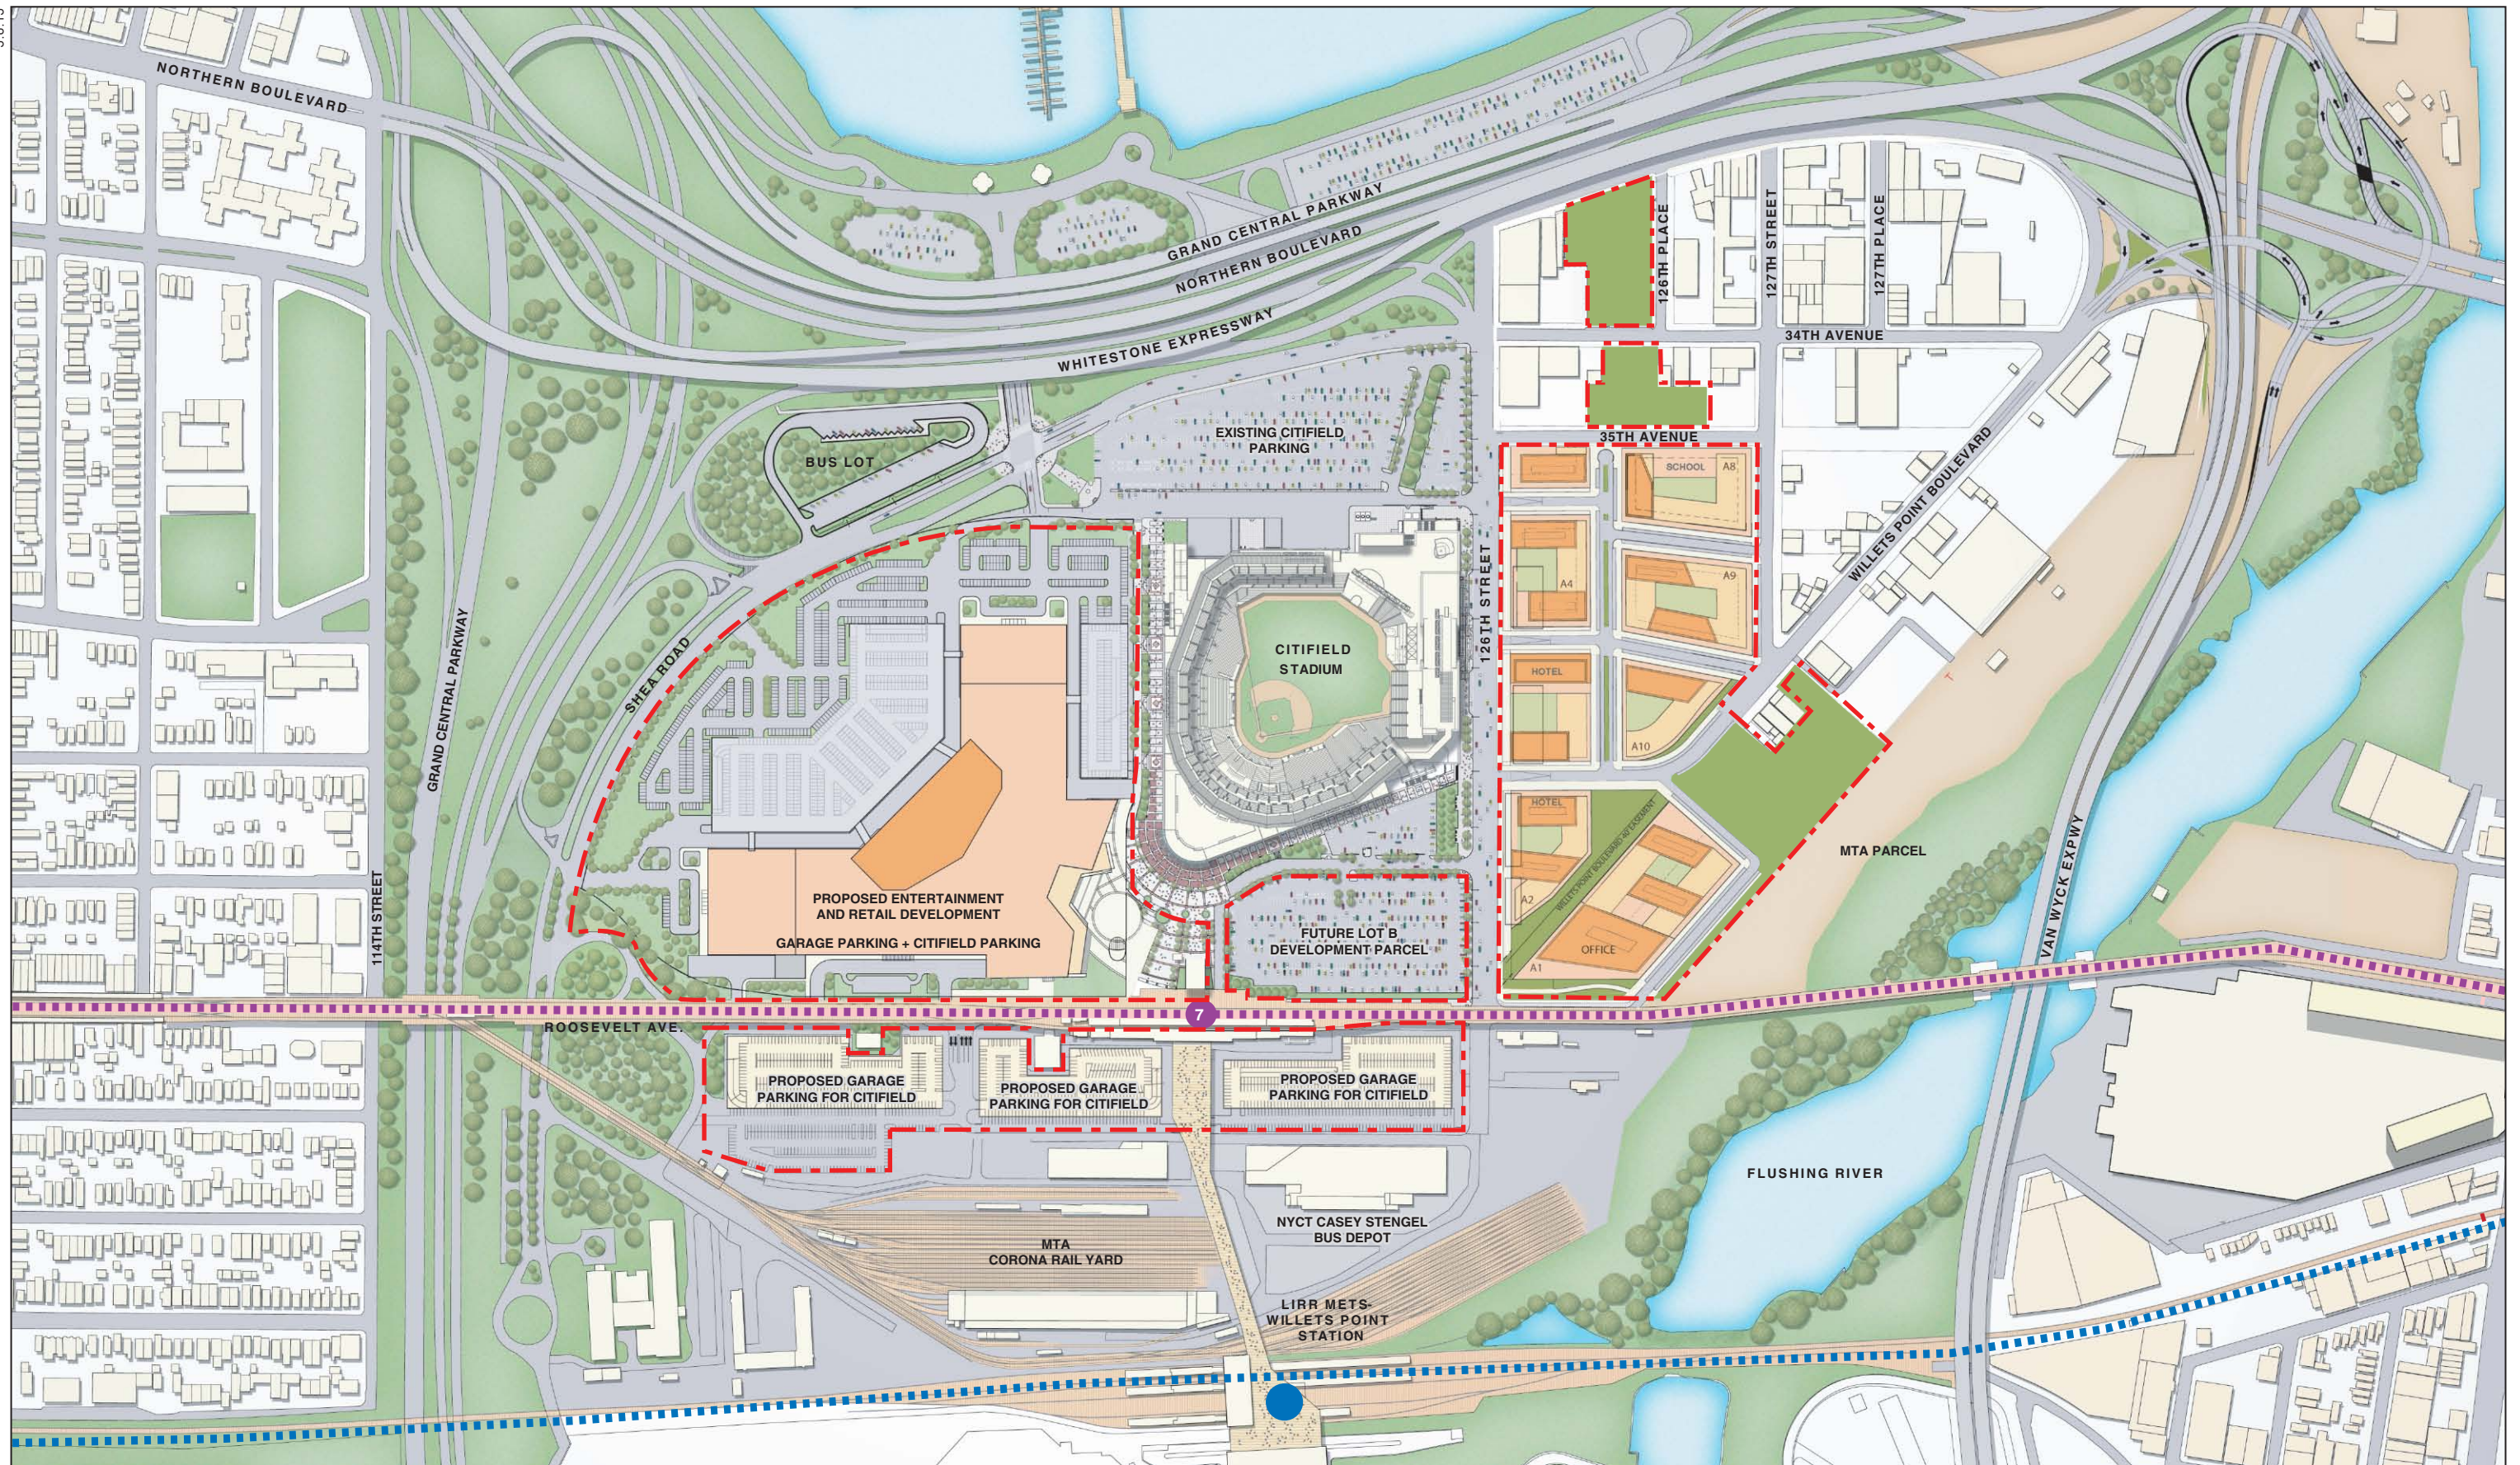

In tandem with the development of the parking area, “Willets West”—an entertainment and retail center of approximately 1.4 million gross square feet (approximately one million square feet of gross leasable area) —would be developed on a portion of the surface parking lot west of CitiField. This entertainment and retail center, which would be developed on mapped parkland as authorized by statute, would allow for more comprehensive transit-oriented development around the Mets/Willets Point stops on the No. 7 train and Long Island Rail Road and would support the economic development of the area. The complex could include over 200 retail stores, including anchor and “mini” anchor retailers, as well as movie theaters, restaurant and food hall spaces, and entertainment venues. Surface parking and a parking structure also would be developed in this location, including 2,500 new spaces for the entertainment/retail center and 400 spaces of replacement parking for use by the Mets. It is anticipated that the Willets West development, by building a critical mass of uses, would create a new destination that would serve as a catalyst for the subsequent build-out of the Willets Point area. In addition, the westernmost CitiField surface parking lot south of Roosevelt Avenue (a portion of the South Lot) would be redeveloped as a structured parking facility, to replace a portion of the CitiField parking spaces formerly located on the Willets West site. Phase 1A is expected to be completed by 2018.

PHASE 1B

In the next phase of the project, the interim surface parking lot/recreational space created during Phase 1A within the Special Willets Point District would be developed, transforming this formerly contaminated area into a new neighborhood. Consistent with the goals and objectives of the Willets Point Development Plan, Phase 1B of the proposed project would create more development on the east side of 126th Street, featuring a more active, attractive streetscape, providing new jobs, and complementing the adjacent CitiField. In addition, the new development would complement the new Willets West development created in Phase 1A. The residential units to be developed in this phase (which include affordable housing units) would accommodate a portion of the City’s current and future housing needs, and the proposed school would address the project-generated school seat demand.

The program for this development would include approximately 4.23 million square feet of development: 2.49 million sf of residential use (2,490 units, 872 of which would be affordable), 875,000 sf of retail use, 500,000 sf of office use, approximately 235,000 sf of hotel use (290 rooms), 25,000 sf of community facility use, and a 105,000 sf public school, along with parking and more than six acres of new public open space (see **Figures 1-4** and **1-5**). This development is anticipated to be developed block by block, substantially as envisioned in the Willets Point Development Plan. In addition, new structured parking facilities would be constructed on portions of the CitiField leasehold along Roosevelt Avenue (South Lot and Lot D) to replace the 2,750 CitiField parking spaces formerly located within the Special Willets Point District. The 75 accessory parking spaces created in Phase 1A for the hotel would remain in the District.

Construction of the new Van Wyck Expressway access ramps—which was anticipated in the 2008 FGEIS and for which the City has received approval from the Federal Highway Administration—is slated to be completed in 2024. Construction of the Phase 1B program is

Publicly-Accessible Open Space within the Special Willets Point District

Private Open Spaces within the Special Willets Point District

Existing Conditions

Illustrative rendering of Phase 1A

Illustrative rendering of Phase 1B

anticipated to take four years; however, the buildings within the District are not expected to be occupied until after the ramp improvements have been completed. The ramps would be operational prior to the occupancy of the Phase 1B buildings. Phase 1B is expected to be completed by 2028.

PHASE 2

In Phase 2, the remainder of the Special Willets Point District would be built out substantially as described in the 2008 FGEIS. Upon completion of Phase 2, the full build-out of all phases of the District is anticipated to total approximately 8.94 million square feet of development, including: up to 5.85 million gsf of residential use (approximately 5,850 units, 2,048 of which would be affordable); up to 1.25 million gsf of retail; approximately 500,000 gsf of office; up to 400,000 gsf of convention center use; up to 560,000 gsf of hotel use (approximately 700 rooms); up to 150,000 gsf of community facility use; approximately 230,000 gsf of public school use; and a minimum of 8 acres of publicly-accessible open space. The number of proposed parking spaces within the District would be determined based on project-generated demand, but is anticipated to be no more than the 6,700 spaces identified in the 2008 FGEIS. Remediation of the portions of the District not already developed in Phases 1A and 1B is assumed to be completed prior to 2028. As with Phase 1B, Phase 2 is anticipated to be completed incrementally over four years, with full build-out expected to be completed by 2032. A developer for Phase 2 has not yet been selected. Phase 2, illustrated in **Figure 1-6**, assumes a similar generic programming to that analyzed in the 2008 FGEIS, while Phase 1A and Phase 1B have discrete programs and designs.

Table 1-1 below provides a summary of the proposed program, by phase, with a summary of the proposed new parking and relocation of existing CitiField parking shown in **Table 1-2**.

COMPARISON OF SEIS AND FGEIS

The actions requested to facilitate the proposed project would not change the maximum overall development of 8.94 million square feet permitted within the District. However, the proposed project would differ from the development analyzed in the 2008 FGEIS in that the FGEIS program did not include any development outside of the District and did not anticipate the use of the District for surface public parking and recreation. Accordingly, the SEIS will analyze 1.4 million gross square feet (1 million leasable square feet) of retail that would be developed at Willets West, the interim parking and recreational uses that would occur within the District, and the proposed parking garages at Willets West, the South Lot, and Lot D. Given the retail development that would occur in Willets West, it was assumed that less destination retail would be developed within the District, so this SEIS analyzes 1.25 million square feet of retail within the District rather than 1.7 million square feet. Although the residential program and its projected population have not changed since the 2008 FGEIS (as analyzed in the No Convention Center Scenario), an increase of 100,000 square feet of school space is assumed in this SEIS to reflect updated projections of increased school seat demand citywide and in particular in Queens. See **Table 1-3** for a comparison of the proposed project for the District vs. the program analyzed in the 2008 FGEIS. Any uses not noted below are not proposed to change from the program analyzed in the 2008 FGEIS.

WW = Willets West

"CitiField" parking is the total number of spaces within the project site that either currently or would in the future serve events at CitiField. Existing Willets West spaces lost to development would be replaced as shown, in Phases 1A and 1B.

"New" parking is the total number of parking spaces that would serve the proposed project.

*These reflect newly developed spaces for Phase 1A, Phase 1B and Phase 2 (2,750 Mets spaces would be relocated to South Lot/Lot D in Phase 1B).

Table 1-3
Totals by Use in Special Willets Point District
Proposed Program vs. 2008 FGEIS

Use	FGEIS	Proposed Program
Retail	1,700,000	1,250,000
Residential	5,550,000 [5,500 units] (<i>Convention Center Scenario</i>) 5,850,000 [5,850 units] (<i>No Convention Center Scenario</i>)	5,850,000 [5,850 units]
Public School	130,000	230,000

The 2008 FGEIS analyzed a Staged Acquisition Alternative, in which the western portion of the District was assumed to be developed by 2013 and the remaining portion of the District would be built out by 2017. Technical Memoranda #3 and #4 also considered the phasing of development in the District over two analysis years. In comparison, this SEIS analyzes the development of the proposed project over three analysis years (2018, 2028, and 2032).

PURPOSE AND NEED

As described above, the proposed project would remediate and transform the area surrounding CitiField. The proposed entertainment and retail destination of Willets West would complement the anticipated development within the District, and both would connect Flushing to the east with Corona to the west through the creation of an unbroken series of uses along Roosevelt Avenue stretching from east of the Flushing River to west of the Grand Central Parkway. Over 2,000 units of affordable housing would be developed to accommodate a portion of the City's current and future affordable housing needs. The project's retail components would capture spending that currently is lost to the surrounding suburbs, and would thereby strengthen economic activity in the neighborhood, borough, and City. The proposed project would represent a significant investment by the City to improve the infrastructure of the project area. Raising the District portion of the project site out of the floodplain would not only minimize the potential loss of life, structures, and natural resources caused by flooding and erosion, but would also protect the City's new infrastructure investment. Eliminating flooding within the District and improving the quality of the soil substrate on the site would also improve water quality in Flushing Bay.

DISCRETIONARY ACTIONS SUBJECT TO CEQR AND SEQRA

The proposed project would require multiple City and State approvals. These anticipated approvals may include:

- Zoning text amendment to ZR Section 124-60 to allow use modifications as part of a phased development within the Special Willets Point District;
- Special permit pursuant to ZR Section 124-60 to allow surface parking/open and enclosed privately operated recreation uses for Phase 1A within the Special Willets Point District;
- Modification of the existing lease for the CitiField property and adjacent parking properties;
- Mayoral and Queens Borough Board approval of the business terms pursuant to New York City Charter Section 384(b)(4);

Willets Point Development

- Approval by the New York City Industrial Development Agency (IDA) or other government agencies for the waiver of mortgage recording tax for property within the Special Willets Point District; and
- A minor modification of the previously approved changes to the City Map to modify the staging for the closure of City Streets. This modification would not result in the demapping of any additional City streets beyond those previously approved for demapping.

In addition to the discretionary approvals listed above, Public Design Commission approval also will be required for the Willets West development. In addition to the above approvals, confirmation that all proposed buildings fall within the maximum Federal Aviation Administration (FAA) height limitations would be sought from the FAA; however, no approval or permit to exceed such permitted heights is anticipated to be sought.

D. ANALYTICAL FRAMEWORK FOR ENVIRONMENTAL REVIEW

OVERVIEW

The SEIS for the development of the project site will supplement the 2008 FGEIS. The SEIS will contain:

- A description of the proposed project and its environmental setting;
- A description of the evolution of project site conditions since 2008;
- The identification and analysis of any significant adverse environmental impacts of the proposed project, including the short- and long-term impacts;
- An identification of any significant adverse environmental impacts that cannot be avoided if the proposed project is implemented;
- A discussion of reasonable alternatives to the proposed project;
- An identification of irreversible and irretrievable commitments of resources that would be involved in the proposed project, should it be implemented; and
- The identification and analysis of practicable mitigation to address any significant adverse impacts generated by the proposed project not previously identified in the FGEIS.

ANALYSIS APPROACH

Each chapter of the SEIS first summarizes the conclusions of the 2008 FGEIS and subsequent technical memoranda for that particular technical area. Then, the chapter assesses whether changes in the analysis years and background conditions, variations between the proposed project and the redevelopment assumed in the 2008 FGEIS, and new proposed actions could result in new or different significant adverse impacts than those disclosed in the 2008 FGEIS. Existing conditions are updated as necessary and presented. Next, the chapter projects changed existing conditions forward into the future without the proposed project, incorporating the most recent information available on known land-use proposals and, as appropriate, changes in anticipated overall growth. Finally, the future with the proposed project is described, the differences between the future without and with the proposed project are measured, and any significant adverse environmental impacts are disclosed. To the extent that specific discretionary actions or program elements could potentially alter the conclusions in the 2008 FGEIS and subsequent technical memoranda, the SEIS focuses on evaluating the potential significant

adverse impacts of those actions or elements. The SEIS also identifies and analyzes appropriate mitigation for any significant adverse environmental impacts.

As noted above, while the 2008 FGEIS was prepared in accordance with the guidelines set forth in the 2001 *CEQR Technical Manual*, this SEIS addresses the updated guidance and analysis methodologies provided in the 2012 *CEQR Technical Manual*.

REASONABLE WORST-CASE DEVELOPMENT SCENARIO

The proposed program detailed above, along with the potential development analyzed in the 2008 FGEIS for Lot B, is analyzed as the reasonable worst-case development scenario (RWCDS) in the SEIS. It is currently anticipated that the assemblage of land within the Special Willets Point District for the Phase 1A and Phase 1B developments could take one of two forms, as shown in **Figure 1-7**. As shown, both assemblage options would include Block 1823 (Lots 19, 20, 21, 23, 26, 28, 33, 40, 44, 47, 52, and 55) Block 1824, Block 1825, Block 1826, Block 1827, Block 1833 (Lots 117, 111, 103, 120, 141, 143, 151, 155, 158, and 172), and Block 1822, Lot 17. In addition to the land common to the two assemblage options, Assemblage Option 1 would include the remaining lots on Block 1823, that is Lots 1, 3, 5, 7, 12, 14, 58, 59, and 60. Assemblage Option 2 would not include the land specific to Assemblage Option 1, but would instead include Lots 9 and 18, on Block 1820. In either scenario, the assemblage would total approximately 23 acres. However, for the purposes of a conservative analysis, the SEIS assumes that all of the potential project site area, totaling 25 acres, would be utilized for surface parking/off-season recreational use in Phase 1A and for development in Phase 1B. For Phase 2, the SEIS assumes that all land comprising both assemblage options taken for Phases 1A and 1B has been developed.

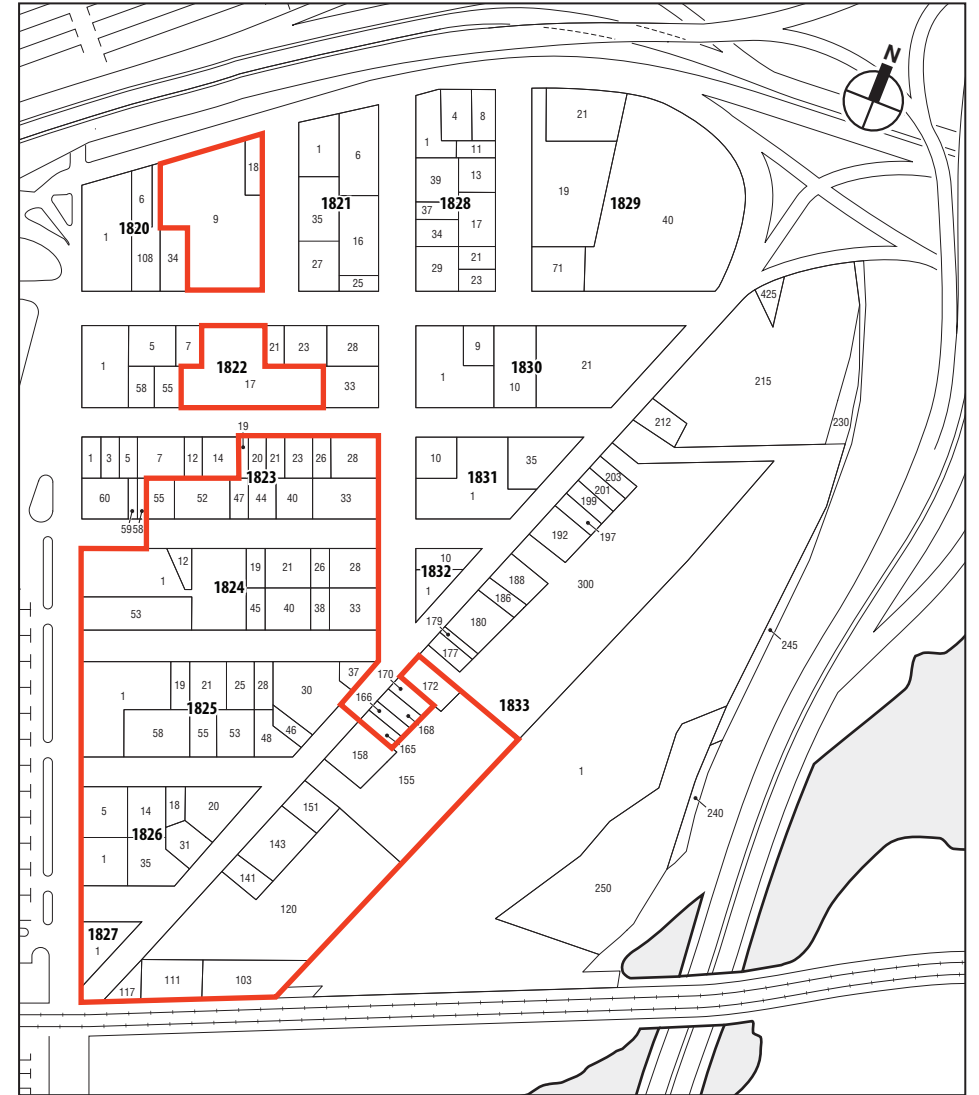

As noted above, the SEIS analyzes the potential development of parking, retail and office uses on Lot B, a portion of the CitiField leasehold along Roosevelt Avenue. The 2008 FGEIS anticipated that if the Willets Point Development Plan were approved and the District were redeveloped into a new mixed-use community and regional destination, additional development could occur on this lot. Any such program for Lot B would require an amendment to the current lease agreement and discretionary approval by IDA, acting through the New York City Department of Parks and Recreation (DPR), which administers the IDA lease. This action would be the subject of a separate environmental review process subject to SEQRA and/or CEQR. This potential development is not part of the proposed program, and no specific development plans have been proposed; however, for the purposes of a conservative analysis, a conceptual program for Lot B will be analyzed as part of the RWCDS. The conceptual program to be analyzed is the same as proposed in the 2008 FGEIS: 184,500 sf of retail use and 280,000 sf of commercial use, which could include a one-story retail structure and a 10-story office building. The existing VIP/ADA parking spaces on Lot B are assumed to be replaced on site; accessory parking for the Lot B development is assumed to be included on Lot D, as analyzed in the 2008 FGEIS. For the purposes of the RWCDS, it is assumed that this development would be completed by 2032.

STUDY AREAS

Each technical study must address impacts within an appropriate geographical area. These “study areas” vary depending on the technical issue being addressed. In most cases, the study areas for the SEIS for impacts arising from the proposed project are different than those presented in the 2008 FGEIS because the geographic extent of the project site for the SEIS will extend west of West 126th Street.

Assemblage Option 1

Assemblage Option 2

0 200 400 FEET
SCALE

FUTURE ANALYSIS YEAR AND BASELINE CONDITIONS

The analysis of the proposed project is performed for the expected year of completion of full build-out of the project, which is anticipated to be 2032. However, some project elements are anticipated for completion by 2018 and 2028, and those elements could result in significant adverse impacts prior to completion of the full development program. While the construction of the Phase 1B program is anticipated to take four years, the buildings within the Special Willets Point District are not expected to be ~~occupied~~constructed until the Van Wyck Expressway ramp improvements have been completed, which is slated to be in 2024. Therefore, three future baseline conditions are examined under the “future without the proposed project” in all technical chapters: the 2018, 2028, and 2032 No Action scenarios. For the purposes of a conservative analysis, this SEIS assumes that the existing uses on the project site would be maintained in each of the three No Action scenarios. *

A. INTRODUCTION

This chapter assesses whether any changed background conditions or the differences between the reasonable worst-case development scenario (RWCDs) and the program assessed in the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda would result in any significant adverse impacts on land use, zoning, and public policy that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

Consistent with the 2008 FGEIS and subsequent technical memoranda, this analysis finds that the proposed project would not result in any significant adverse impacts to land use, zoning, or public policy.

As anticipated in the 2008 FGEIS, the proposed project would dramatically change land uses in the Special Willets Point District by replacing predominantly low-density, auto-related, and industrial uses with a new mixed-use neighborhood. The proposed project also would constitute a significant change for the Willets West portion of the project site by replacing a surface parking field with a new entertainment and retail center of approximately 1.4 million gross square feet (gsf) (approximately one million square feet (sf) of gross leasable area). New structured parking facilities would be built on the South Lot and Lot D to accommodate a portion of the parking for Mets patrons relocated from the Willets West surface parking field. The potential future development of Lot B is the same as projected in the 2008 FGEIS.

While the proposed project would result in significant land use changes on the project site, the effects of this change would not be adverse. The District would create a dynamic, sustainable community by integrating regional attractions and residential, retail, and other uses within a network of pedestrian-scaled streetscapes. The previously approved zoning regulations would continue to determine elements such as the placement of uses within the District, building heights and setbacks, street controls (i.e., mandatory intersections and street types), streetscape design, and basic site planning and design provisions. The Willets West portion of the project would create a regional entertainment and retail destination center that would support and be compatible with the new uses in the District as well as uses in the surrounding area.

Consistent with the 2008 FGEIS, the proposed project represents a critical step in implementing the 2004 Downtown Flushing Development Framework, a land use and economic planning strategy for the growth of Downtown Flushing, the Flushing waterfront, and adjacent areas. The District would be developed pursuant to the zoning regulations approved in 2008, and the proposed project would advance a number of the Framework's fundamental goals, including the creation of a regional destination that would enhance economic growth in Downtown Flushing; improvement of environmental conditions; and integration of new development with surrounding amenities, including the Flushing Bay Promenade, CitiField, Flushing Meadows-

Corona Park, and Downtown Flushing. The proposed project would be consistent with and vital to the advancement of several of the goals of PlaNYC, which aim to create a more sustainable New York by the year 2030. The proposed project would also be consistent with the coastal policies set forth in the New York City Waterfront Revitalization Program (WRP).

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

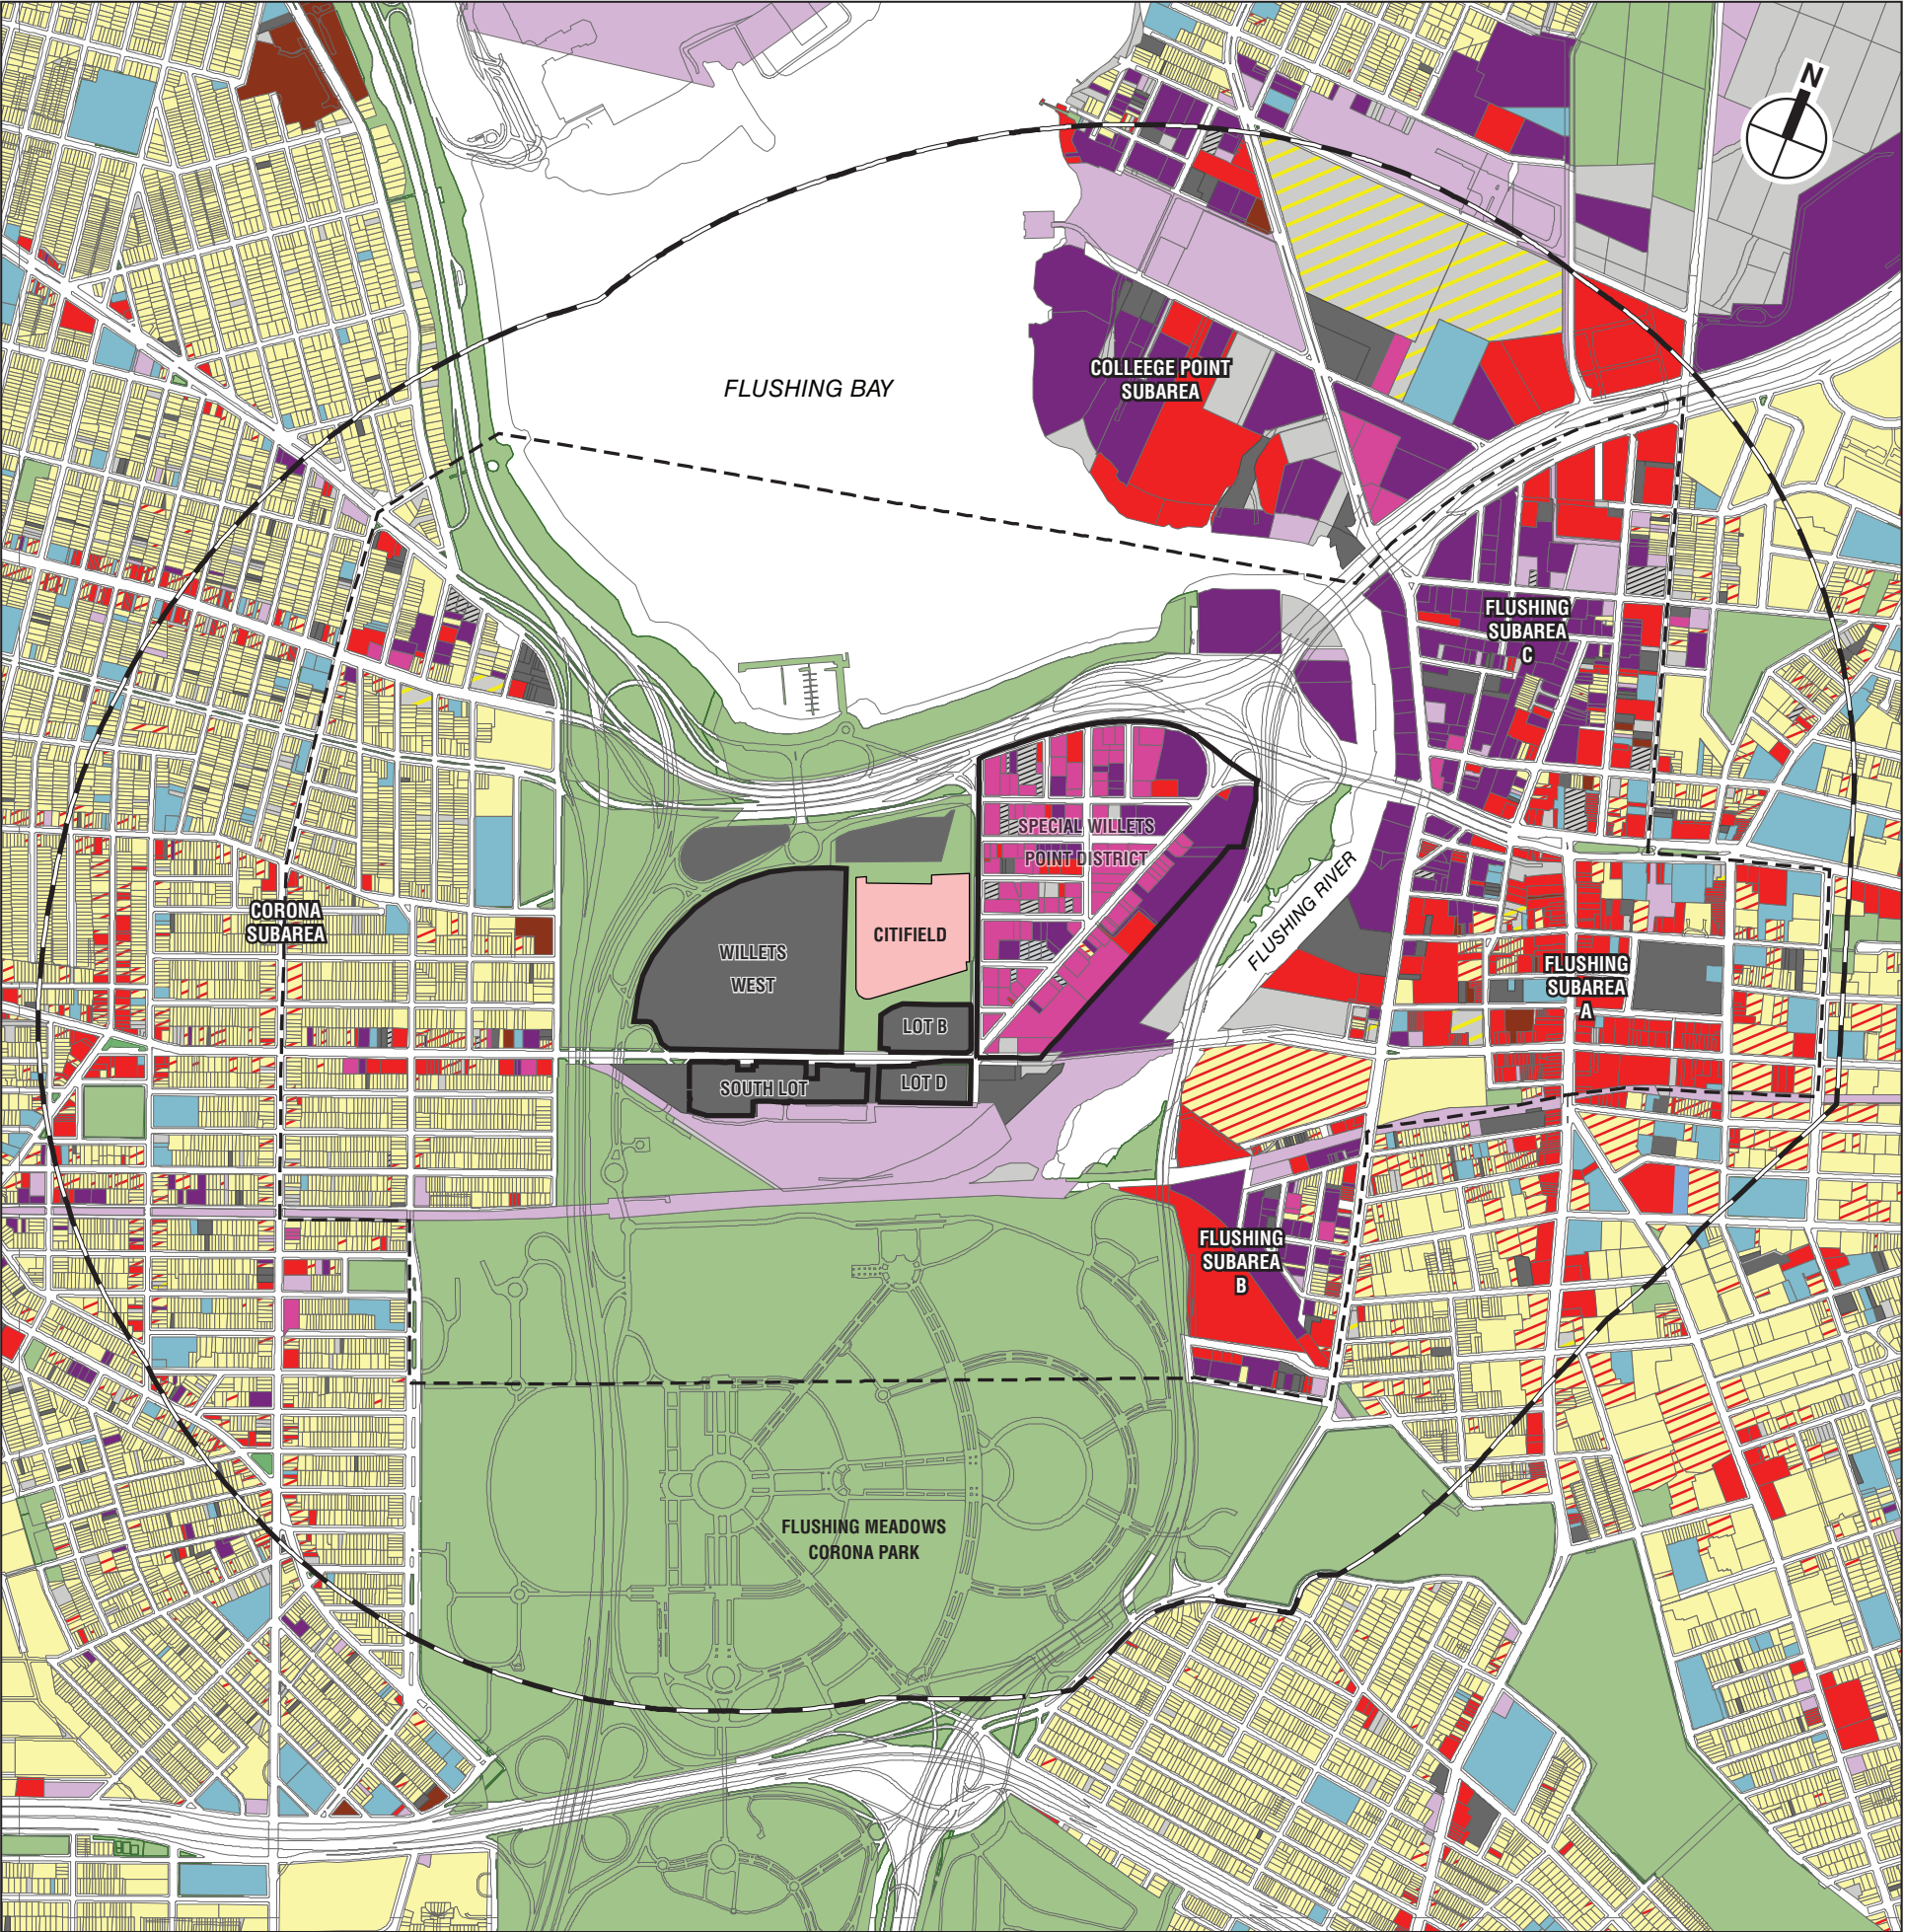

The 2008 FGEIS concluded that, although land uses would dramatically change in the District as a result of the proposed Willeys Point Development Plan (the “Plan”), replacing a predominantly low-density, auto-related and industrial use area with a new mixed-use neighborhood, including community facilities and additional open space, would improve the quality of life for area residents and visitors. Furthermore, the proposed convention center and commercial uses would enhance Flushing and Corona’s roles as regional economic centers, and would attract visitors to the area, and the proposed Plan would create a pedestrian-oriented regional entertainment and commercial center along 126th Street, which would complement the new retail uses planned along the west side of 126th Street as part of CitiField, creating synergy between CitiField and the proposed District. The 2008 FGEIS also noted that the proposed redevelopment represented a critical step in implementing the 2004 Downtown Flushing Development Framework strategy for the Flushing River waterfront and the Willeys Point peninsula. Therefore, the 2008 FGEIS concluded that the proposed Plan would not have any significant adverse impacts on land use, zoning, or public policy on the project site or study areas. Subsequent technical memoranda also concluded that the proposed revisions to the Plan would not have significant adverse impacts on land use, zoning, or public policy on the project site or study areas.

C. METHODOLOGY

This chapter has been prepared in accordance with the guidelines of the 2012 *City Environmental Quality Review (CEQR) Technical Manual*. It describes existing land use conditions and future conditions without the proposed project, and analyzes the probable impacts that the proposed project may have on land use, zoning, and public policy. Because of the scale of the proposed project, this analysis considers both a primary and secondary study area. The primary study area is the area generally located within ½ mile from the project site, and includes Downtown Flushing, portions of Flushing Meadows-Corona Park, and portions of Corona adjacent to Flushing Meadows-Corona Park (see **Figure 2-1**). The secondary study area is generally located between ½ and ¾ mile from the project site and includes portions of the Corona, College Point, and greater Flushing neighborhoods. The boundaries of the secondary study area generally extend from Bowne Street in Flushing to the east to 101st Street in Corona to the west, 28th Avenue in College Point to the north, and the Long Island Expressway (LIE) in Flushing Meadows-Corona Park to the south.

The primary and secondary land use study area boundaries are not defined solely by the ½- and ¾-mile radii around the project site, but rather reflect natural and manmade barriers and current land use patterns. Portions of several neighborhoods fall within the study area boundaries. Therefore, the impact analysis addresses several sub-areas as follows:

- **Flushing Subarea:** This area extends east of the Flushing River from Kissena Corridor Park to the Whitestone Expressway. The land use and zoning discussion below separates the Flushing Subarea into three sections, which generally reflect the different land use patterns

- Willets Point Development District Boundary
- - - Primary Study Area Boundary
- Secondary Study Area Boundary

- Residential
- Residential with Commercial Below
- Hotels
- Commercial and Office Buildings
- Public Facilities and Institutions
- Entertainment
- Auto-Related Use
- Industrial and Manufacturing
- Transportation and Utility
- Open Space and Outdoor Recreation
- Parking Facilities
- Vacant Land
- Vacant Building
- Under Construction

within the overall area, as follows: the area between the Long Island Rail Road (LIRR) tracks and Northern Boulevard (Flushing Subarea A); the area between the LIRR tracks and Kissena Corridor Park (Flushing Subarea B); and the area between Northern Boulevard and the Whitestone Expressway (Flushing Subarea C).

- Although a portion of Downtown Flushing (Flushing Subarea A) is located outside of the ½-mile primary study area boundary, the entire Downtown Flushing area is considered to be within the primary study area, as a cohesive district. In Flushing Subarea B, College Point Boulevard is approximately ½ mile from the District, and generally divides into distinct land use patterns; in light of this, the area to the west of College Point Boulevard is considered to be within the primary study area, and the area to the east is considered to be within the secondary study area. Similarly, in Flushing Subarea C, Linden Place is approximately ½ mile from the District and generally divides into distinct land use patterns; similarly, the area to the west of Linden Place is considered within the primary study area, and the area to the east is considered within the secondary study area.
- Corona Subarea: This area is roughly bounded by the Grand Central Parkway to the north, 55th Avenue to the south, 101st Street to the west, and 114th Street to the east. The Corona Subarea is located within both the ½- and ¾-mile radii around the project site, and is therefore considered in both study areas.
- College Point Subarea: This area extends south of 28th Avenue and west of the Whitestone Expressway to Flushing Bay. While a portion of College Point is located within ½ mile of the District, the entire College Point Subarea is considered within the secondary study area, as it is physically separated from the District by Flushing Bay and the Whitestone Expressway.
- Flushing Meadows-Corona Park: The park area considered within the primary study area is roughly within the ½-mile radius around the project site. The park area considered within the secondary study area includes the remainder of the park to the north of the LIE (which is beyond the ¾-mile radius), to reflect the intrinsic cohesiveness of the amenities and uses in that section of the park.

This analysis assesses future conditions in 2018, 2028, and 2032, when full buildout of the RWCDs is anticipated.

D. EXISTING CONDITIONS

LAND USE

PROJECT SITE

The project site is composed of three discrete areas—the Special Willets Point District (the “District”), Willets West, and three surface parking lots along Roosevelt Avenue (“Roosevelt Avenue”)—which are roughly bounded by Shea Road and Northern Boulevard to the north, the Van Wyck Expressway to the east, Roosevelt Avenue and the Metropolitan Transportation Authority (MTA) Corona Rail Yard to the south, and Shea Road to the west.

Special Willets Point District

The District portion of the project site comprises approximately 61 acres, approximately 15.8 acres of which are within public street rights-of-way, approximately 0.6 acres of which are owned by MTA, and the remainder of which is a mix of privately owned land and City-owned

Willets Point Development

land. The District comprises 128 tax lots and one partial lot (Block 1833, Lot 1) located on 14 blocks. Since the FGEIS was completed in 2008, the City has acquired, or is in contract to purchase 95 percent of the land area within the proposed Phase 1A/1B footprint (Assemblage Option 2), and has control of 4 lots in the remainder of the District.

Land uses in the District primarily consist of auto-related services and industrial uses. Auto-related services are the most prevalent use in the District. These services consist of auto-body repair, auto glass, car washes and auto detailing, used and new auto part sales, tire sales, and vehicle towing. For the most part, these auto-related businesses occupy one-story garage buildings and Quonset-type structures, many of which contain multiple auto-related businesses. There are also a number of car junkyards in the District, which support auto salvage businesses.

The District also contains some industrial uses, including construction-related services and materials, and waste transfer and recycling. Lot areas in the District vary greatly in size and range from approximately 2,000 to 173,000 sf; the industrial uses generally occupy the larger lots. Two waste transfer businesses (Tully Environmental and Crown Container) are currently operating in the portion of the District that would be developed in Phase 2. Tully Environmental and Crown Container process putrescible waste, and construction and demolition debris. One large food production and distribution use—House of Spices—is located in the portion east of Willets Point Boulevard in the portion of the District that would be developed in Phase 2. One recycling business—Metal Green Recycling—is located on a City-owned parcel in the District north of 34th Avenue that would be developed in Phase 1A/1B. Several undeveloped lots in the District all contain either open-air storage of construction materials or used auto parts.

In addition to the auto-related and industrial uses, a few commercial uses exist in the District to cater to businesses in the area. These include a deli and grocery, and a restaurant. The District contains one institutional use, a private, members-only motorcycle club. Although residential uses are not permitted under the existing zoning, there is one residential unit in the District, located on Willets Point Boulevard.

Existing uses in the District consist of predominantly auto-related uses located in buildings with small footprints, with some commercial and manufacturing uses located throughout the District. In contrast, industrial uses along the Flushing River and Flushing Bay from Whitestone Expressway to approximately 37th Avenue consist primarily of manufacturing and industrial uses located on large lots in buildings with large footprints. These industrial and manufacturing uses contrast sharply with most of the uses and types of development in the nearby communities, such as the higher-density commercial and residential development in Downtown Flushing, and the primarily low- to mid-density residential neighborhood of Corona to the west of CitiField and the Grand Central Parkway. Deteriorated sidewalks, large potholes, corrugated metal building façades, and the widespread use of streets and sidewalks for vehicle parking and storage for adjacent automotive uses contribute to an unappealing streetscape and create uninviting and unsafe pedestrian conditions. Despite its transit-oriented location and proximity to Downtown Flushing and several thriving neighborhoods, Willets Point contains virtually none of the land use characteristics or patterns of its neighbors.

Willets West

The Willets West portion of the project site comprises an approximately 30.7-acre section of the surface parking field adjacent to CitiField, the stadium for the New York Mets. This area comprises a portion of Block 1787, Lot 20. While this portion of the project site is mapped as parkland in Flushing Meadows-Corona Park, it does not function as public open space. It was

occupied by Shea Stadium and associated parking and circulation space until it was replaced by CitiField in 2009; it is now occupied exclusively by surface parking.

Roosevelt Avenue

The Roosevelt Avenue portion of the project site comprises three CitiField-related surface parking lots (South Lot and Lots B and D) along Roosevelt Avenue. These lots are also mapped as parkland, but are occupied exclusively by surface parking. The Lot B parking lot, which comprises a portion of Block 1787, Lot 20 (north of Roosevelt Avenue), is approximately 4.7 acres in size; the South Lot and Lot D parking lots (south of Roosevelt Avenue), which comprises a portion of Block 2018, Lot 1500, are collectively approximately 12.1 acres in size. Lot D and South Lot are used for commuter parking and United States Tennis Association (USTA) National Tennis Center (NTC) events when baseball games are not in progress. Lot B is used as player and staff parking for CitiField events.

In total, the project site comprises approximately 108.9 acres.

The project site is mostly isolated from the surrounding neighborhoods by several natural and manmade barriers. The Flushing River lies to the east of the Van Wyck Expressway and beyond it, Downtown Flushing. North of Northern Boulevard is Flushing Bay, with the industrial area of College Point on its northern shore. To the south of the project site are the LIRR tracks for the Port Washington Line, the MTA Corona Rail Yard, and the USTA NTC, and to the west are located the Grand Central Parkway and the Corona neighborhood.

PRIMARY STUDY AREA

The primary study area includes portions of Flushing Meadows-Corona Park, Downtown Flushing, the greater Flushing area, and portions of Corona. Also included in the primary study area are the other uses on the Willets Point peninsula that lie outside the District. Directly east of the District is a large, undeveloped MTA property located along the Flushing River waterfront, a majority of which is leased to Tully Environmental, Inc., which operates a construction and demolition debris recycling operation on the site. To the north of the District, across Northern Boulevard, is a New York City Department of Transportation (NYCDOT) maintenance and repair facility, and between Northern Boulevard and the Van Wyck Expressway is an asphalt plant. To the northwest of the District, across Northern Boulevard, is the Flushing Bay Promenade, which lies within the boundary of Flushing Meadows-Corona Park and is described below. To the south of the District—south of Roosevelt Avenue, near the LIRR tracks—is the MTA Corona Rail Yard. The Corona Rail Yard, which is not part of Flushing Meadows-Corona Park, contains a storage area for subway cars as well as repair shops. The Casey Stengel Bus Depot is adjacent to the Corona Rail Yard.

Flushing Meadows-Corona Park

Flushing Meadows-Corona Park is a major recreational and cultural destination for Queens residents and visitors from throughout the New York metropolitan area. The park covers approximately 1,255 acres and is under the jurisdiction of the New York City Department of Parks and Recreation (DPR). The park is roughly bounded by several major thoroughfares: the Grand Central Parkway to the west, the Van Wyck Expressway to the east, and the beginning of the Whitestone Expressway to the north.

The primary study area includes the portion of the park that extends from Flushing Bay to just south of the USTA NTC. This portion of the park includes CitiField and its surrounding parking

Willets Point Development

fields. The elevated No. 7 subway line serves the primary study area, with the Mets-Willets Point station located adjacent to CitiField above Roosevelt Avenue. The LIRR also has a Mets-Willets Point station adjacent to the Corona Rail Yard, which operates on baseball game and USTA NTC event days. The Passerelle Ramp, which is for pedestrian use, spans the rail yard and connects both stations to CitiField and the USTA NTC.

The USTA NTC contains three stadiums and is host to tennis events year-round, including the U.S. Open. The USTA NTC contains the 23,000-seat Arthur Ashe Stadium, 10,000-seat Louis Armstrong Stadium, a smaller 3,500-seat stadium, and 30 additional tennis courts. The courts are open during the year for tennis clinics and camps, as well as for general public use. There is a small parking lot located adjacent to the USTA NTC; however, during the U.S. Open, CitiField lots are also used for parking.

East of the USTA NTC, the park contains a pitch and putt golf center, and a large area for passive and active recreation, with trees, pathways, and seating areas. West of the USTA NTC and the Grand Central Parkway, the park includes the New York Hall of Science. There is a large (500-space) parking lot adjacent to the museum. The Olmsted Center, located near the LIRR right-of-way immediately west of the USTA NTC, contains offices for the design and construction supervision divisions of DPR. The Passerelle Building, located under the Passerelle Ramp, contains offices and support facilities for the park. The Allied Building, located on the far-east side of the park south of Roosevelt Avenue and near the Van Wyck Expressway, contains DPR offices and storehouses.

To the north of Northern Boulevard is the Flushing Bay Promenade, which winds along Flushing Bay for approximately 1.4 miles from LaGuardia Airport to the Willets Point peninsula. The promenade contains many seating areas and provides access to the World's Fair Marina and a restaurant located northeast of CitiField. There are more than 1,000 parking spaces located to the east and west of the marina, which are also available for parking on Mets game days.

Flushing

Flushing is a thriving business and residential area known for its Asian goods and culture. Downtown Flushing and the greater Flushing area are home to a significant Chinese and Korean population, and there are many specialty food and retail stores, restaurants, and other services that are utilized not only by local residents, but also serve as a destination for people living outside of the community. The primary study area in Flushing contains Downtown Flushing, a regional transportation and commercial hub for Queens. While most of the commercial and cultural activity is centered along Northern Boulevard, Roosevelt Avenue, and Main Street, the Downtown Flushing study area (Flushing Subarea A) generally extends between the Flushing River to the west, Northern Boulevard to the north, Bowne Street to the east, and the LIRR tracks located south of Roosevelt Avenue to the south. Also located within the primary study area are the predominantly industrial areas in Flushing which are generally located along the Flushing River within approximately ½ mile of the District, with some commercial and mixed-uses areas south of 37th Avenue. To the south of the LIRR Port Washington Line (Flushing Subarea B), industrial uses are concentrated west of College Point Boulevard. To the north of Northern Boulevard (Flushing Subarea C), a large industrial district extends east of the Flushing River to Linden Place.

Downtown Flushing—Flushing Subarea A

Downtown Flushing is a center of commercial and cultural activity in Queens, and contains many Asian specialty food stores, restaurants, and retail stores that cater to the local population

and serve as a regional destination. Commercial uses predominate and are concentrated along Roosevelt Avenue, Northern Boulevard, Main Street, Union Street, and Prince Street. Industrial uses are mostly located west of College Point Boulevard along the Flushing River. Some residential and community facility uses are scattered throughout Downtown Flushing. East of Union Street, the neighborhood begins to transition to a more predominantly residential area.

The Downtown Flushing area has been changing in character in recent years, as more high-density residential and large-scale mixed-use developments are either under construction or planned throughout the area. Queens Crossing, a recently completed large mixed-use development, is located between Main and Union Streets, north of 39th Avenue. Another large mixed-use development planned in this area is Flushing Commons. Two large mixed-use developments—Sky View Parc Phase II and River Park Place—are planned on sites located near the Flushing River. These and other planned development projects are described below in Section D, “Future without the Proposed Project.”

Residential Uses.

Residential uses in Downtown Flushing are primarily located east of Union Street, where the neighborhood becomes more residential in character. In this area, residential uses primarily consist of mid-rise apartment buildings between 6 and 10 stories with retail uses on the ground floor, as well as three-story rowhouses, some of which contain ground-floor retail uses. Some residential uses are interspersed between the commercial uses in Downtown Flushing to the west of Union Street. The 400-unit New York City Housing Authority (NYCHA) Bland Houses are located at the southeast corner of Roosevelt Avenue and College Point Boulevard, and a 60-unit residential building is located at the corner of 39th Avenue and College Point Boulevard.

Commercial Uses.

Specialty retail uses are prevalent on most streets in the area, which are lined with numerous retail shops, food establishments, convenience goods stores, and neighborhood services. As mentioned previously, Roosevelt Avenue, Northern Boulevard, Main Street, and Prince Street are the primary commercial corridors in Subarea A. Two major commercial centers, Assi Plaza and the Flushing Mall, are located near the intersection of College Point Boulevard and 39th Avenue and contain a collection of businesses catering to the area’s Asian population. Sky View Center—part of the Sky View Parc development bounded by Whitestone Expressway, 40th Road, College Point Boulevard, and Roosevelt Avenue—is also a major commercial center with several large department and electronic stores and a warehouse club. In addition, a 173-room Sheraton hotel is located on 39th Avenue between Prince and Main Streets.

Manufacturing and Industrial Uses.

Most industrial uses are located west of College Point Boulevard, along the eastern bank of the Flushing River. These include a 110,000-sf U-Haul facility and an asphalt plant that utilizes barges for transporting materials to and from its facility.

Transportation and Utility Uses.

The No. 7 subway line has a terminal station at Roosevelt Avenue and Main Street. The right-of-way for the LIRR Port Washington Line forms the southern boundary of this subarea, with a station located at Main Street and 41st Avenue.

There are several municipal parking lots in Downtown Flushing. Municipal Lot No. 1, located between Union Street, 138th Street, and 37th and 39th Avenues, contains approximately 1,020 public parking spaces, and is the site of a proposed mixed-use development known as Flushing Commons, described below in Section D, “Future without the Proposed Project.” Flushing

Willeys Point Development

Municipal Lot No. 2 is located on the east side of Prince Street between 38th and 39th Avenues and contains approximately 87 parking spaces. Flushing Municipal Lot No. 4 is located underneath the Northern Boulevard viaduct and contains approximately 93 parking spaces.

Community Facilities and Open Spaces.

Notable community facilities in Downtown Flushing include Flushing Town Hall, which is located on Northern Boulevard and is used as a concert hall and cultural center; the Flushing Armory, located on Northern Boulevard, which houses the New York City Police Department (NYPD) Queens North task force unit; the Friends Meeting House, also on Northern Boulevard; and St. George's Church on Main Street between 38th and 39th Avenues. Other community facilities in this area include a YMCA building on Northern Boulevard, the Macedonia African Methodist Episcopal Church located adjacent to Municipal Lot No. 1, and the Flushing House Community Residence, a 319-unit nursing home located on Bowne Street and 38th Avenue.

There are only two publicly accessible open spaces in this area. One is an approximately 1.7-acre area with amenities such as basketball courts, walkways, and benches located within the grounds of the NYCHA Bland Houses at the corner of Prince Street and 40th Road. The other is the approximately half-acre Bland Park located just outside of the NYCHA campus.

Flushing Subarea B

This portion of the primary study area located south of the LIRR right-of-way and west of College Point Boulevard is characterized by a mix of industrial, commercial, and residential uses. Since this area is adjacent to Flushing Meadows-Corona Park and there is no outlet for streets running west of College Point Boulevard, traffic is light on these streets.

Residential Uses.

Residential uses in this area are generally located within one to two blocks of College Point Boulevard and are interspersed with active industrial and commercial uses. The residential uses here are generally low-density, consisting of two-story attached residences, as well as a cluster of single family homes located on Haight Street.

Commercial Uses.

The most prominent commercial use in this area is a 150,000-sf Home Depot, located on Avery Avenue just west of College Point Boulevard. Neighborhood retail establishments are also prevalent along College Point Boulevard, and include small retail service establishments, convenience stores, and fast-food restaurants.

Manufacturing and Industrial Uses.

A variety of light-manufacturing, warehousing, and automotive uses are found in this area, including sign stores, a furniture warehouse, and an auto body repair shop.

Transportation and Utility Uses.

The right-of-way for the LIRR Port Washington Line forms the northern boundary of this subarea, and the Van Wyck Expressway forms the western boundary.

Community Facilities and Open Space.

There are no community facility uses in this subarea. Flushing Meadows-Corona Park, described above, is located both west of the Van Wyck Expressway and south of Fowler Avenue. There are no other publicly accessible open spaces in this area.

Flushing Subarea C

This portion of the primary study area located west of Linden Place between Northern Boulevard and the Whitestone Expressway primarily consists of industrial and manufacturing

uses, with some commercial, office, neighborhood retail, and residential uses generally located east of Prince Street.

Residential Uses.

Residential uses are limited in this area, and are interspersed with surrounding commercial, industrial, and warehouse uses. Residential buildings are primarily located east of Prince Street between 32nd and 35th Avenues. The residential buildings in this area are a mix of single-family attached and detached homes and mid-rise buildings, some of which contain commercial uses on the ground floor.

Commercial Uses.

There is a mix of large commercial uses and dense neighborhood retail and office uses along the two main thoroughfares in this area, the Whitestone Expressway and Northern Boulevard. Commercial uses concentrated along the Whitestone Expressway include fast-food restaurants, a bowling alley, commercial office space, a bank, and a car wash. Large commercial buildings, including auto-related uses and commercial distributing uses, are located west of Prince Street and north of 35th Avenue. Neighborhood commercial and office uses, such as gas stations, restaurants, realtors, and nail salons, are mostly located along Northern Boulevard, and in the area east of Prince Street and south of 35th Avenue.

Manufacturing and Industrial Uses.

Manufacturing and industrial uses are the predominant uses in this area, and include building material companies, such as cement, concrete, lumber and tile, warehousing uses, and some auto-related uses. Some of the heavy industrial uses on the Flushing River waterfront, such as the cement and asphalt operations, use barges to transport materials to and from their sites. The area north of 35th Avenue and west of Prince Street primarily contains warehousing, distribution, and wholesale facilities for specialty Asian goods.

Transportation and Utility Uses.

The Whitestone Expressway forms the northern boundary of this subarea. Utility uses include a DEP sewer maintenance facility, located on Downing Street at 32nd Avenue, and Con Edison maintenance and vehicle storage facilities, located on 32nd Avenue near Farrington Street, as well as on College Point Boulevard near 35th Avenue.

Community Facilities and Open Space.

Community facilities in this area are limited, but include religious facilities such as the Queens Alliance Church, Calvary World Mission, and the Disciples Church of New York. There are no open space areas in this area.

Corona

The portion of the primary study area bounded by 114th Street to the east, 108th Street to the west, Grand Central Parkway to the north, and 44th Avenue to the south primarily consists of residential uses, with some commercial and manufacturing uses concentrated along Northern Boulevard and Roosevelt Avenue.

Residential Uses

This portion of the primary study area is predominantly residential in character and contains a variety of housing types, including detached one- and two-family residences on narrow lots, attached row-houses and multi-family dwelling units, and apartment buildings. Other prominent residential uses include the 301-unit Dorie Miller Cooperative housing development located on

Willeys Point Development

114th Street between Northern Boulevard and 34th Avenue, and the 132-unit Meadow Manor housing development located at 113th Street and 34th Avenue.

Commercial Uses

There is a mix of commercial uses and dense neighborhood retail and office uses along Northern Boulevard and Roosevelt Avenue. Neighborhood commercial uses are located primarily along Roosevelt Avenue, and include realty offices, fast-food restaurants, gas stations, nail salons, grocery stores, clothing stores, discount stores, furniture stores, pharmacies, and restaurants. A few commercial uses are located along Northern Boulevard, including a steakhouse and car dealership. However, recent and anticipated development along Northern Boulevard is establishing more high-density, mixed residential and commercial uses.

Manufacturing and Industrial Uses

A few auto-related uses are located on Northern Boulevard. Some light manufacturing uses are located on 111th Street between Northern Boulevard and Astoria Boulevard, including a live chicken wholesale warehouse and storage warehouse. A construction material distribution warehouse and a few auto-related uses are also located on Roosevelt Avenue.

Transportation and Utility

The right-of-way for the LIRR Port Washington Line forms the southern boundary of this subarea, and the Grand Central Parkway forms the northern boundary. The No. 7 subway line, which is elevated above Roosevelt Avenue, has a station at 111th Street.

Community Facility and Open Space

Notable community facilities in this portion of Corona include the Louis Armstrong School (P.S. 143), located on 37th Avenue between 112th and 113th Streets. Directly opposite is Hinton Park, a 3.7-acre park that stretches from 34th to 37th Avenues between 113th and 114th Streets and features game tables, benches, baseball diamonds, and play areas. Religious facilities include the New York Church of Christ, located at 37-06 111th Street, and Mount Horeb Baptist Church, located at the southwest corner of 34th Avenue and 110th Street. The Child Center of New York day care center is located on Northern Boulevard between 111th and 112th Streets.

SECONDARY STUDY AREA

The secondary study area includes the College Point and Flushing neighborhoods, as well as additional portions of Corona and portions of Flushing Meadows-Corona Park north of the Long Island Expressway. In Flushing and Corona, the secondary study area subareas are extensions of the neighborhoods in the primary study area. The Corona and College Point portions of the study area are separated from the project site either by a substantial distance or by significant natural or manmade barriers.

Flushing Meadows-Corona Park

The portion of Flushing Meadows-Corona Park that falls within the secondary study area contains several cultural institutions housed in buildings dating from the 1939 and 1964 World's Fairs, as well as recreational and sporting facilities, several baseball and soccer fields, and a number of playgrounds. The cultural institutions include the 1939 New York City Pavilion just south of the USTA NTC, which contains the Queens Museum of Art (QMA). The Unisphere sculpture, which has become a symbol for the park and is a New York City Landmark (NYCL), stands directly east of the QMA. The Queens Wildlife Center, Terrace on the Park catering/restaurant facility, and Playground for All Children (a special playground for both able-bodied and disabled children) are located in the portion of the park west of the Grand Central

Parkway, just south of the Hall of Science. The Queens Theatre and Maloof Skate Park are located south of the QMA. An ice rink and natatorium facility are located in the far eastern portion of the park. The southern portion of the park is located south of the LIE and is outside of the land use study area.

In addition to the various cultural institutions, sporting events, and recreational activities in the park, Flushing Meadows-Corona Park is host to numerous festivals and gatherings throughout the year, attracting hundreds of thousands of visitors. Some groups hold daylong events, such as the Peruvian, Colombian, and Dominican festivals. Other well known festivals held in the park are the Hong Kong Dragon Boat Festival, the Korean Harvest and Folklore Festival, and DPR's Spring Festival.

Corona

The predominantly residential neighborhood in the Corona subarea is located west of 108th Street and east of 101st Street between Grand Central Parkway and 53rd Avenue. The subarea's main thoroughfares are Northern Boulevard and Roosevelt Avenue. These corridors, along with 103rd Street from 37th Avenue to 44th Avenue, are lined with neighborhood commercial uses such as delis, grocery stores, retail services, and restaurants. Corona contains a variety of housing types, including detached one- and two-family residences on narrow lots, attached row-houses and multi-family dwelling units, and apartment buildings.

Park of the Americas (Linden Park), bounded by 41st Avenue, 104th Street, 42 Avenue, and 103 Street, is a 3.08-acre park equipped with a ballfield, basketball courts, and playgrounds. The Corona Gold Playground bounded by 46th and 47th Avenue, 109th Street, and the Flushing Meadows-Corona Playground is a 1.7-acre park equipped with basketball courts, fitness equipment, handball courts, and jungle gyms. Notable community facilities include the Louis Armstrong Rehabilitation Center on Northern Boulevard, the BCL Day Care Center on 108th Street, Our Lady of Sorrows Church and School on 105th Street, the Nancy Debeneditis School (P.S. Q016) across from Park of the Americas, St. Leo's Roman Catholic Church on 49th Avenue, and the Thomas Emanuel Early Childhood Center (P.S. 28) on 47th Avenue.

Flushing

The portions of Flushing located in the secondary study area consist of the predominantly residential areas located to the north and south of Downtown Flushing. There are a number of community facility and institutional uses in this subarea, supporting the greater Flushing area. Commercial uses are generally located along main thoroughfares such as Main and Union Streets.

Flushing Subarea B

This subarea is generally located south of the LIRR Port Washington Line and east of College Point Boulevard. Main Street, which divides the area, is the main commercial corridor with retail uses common to Downtown Flushing. The area east of Main Street is characterized by mid-rise residential structures with ground-floor retail interspersed with several large low-rise commercial buildings. The area west of Main Street is primarily residential, with tree-lined streets and low-rise row houses, though recent and ongoing construction activities are replacing some of the low-density residential buildings in this area with new, higher-density development.

Institutional uses are primarily concentrated east of Main Street and include the Flushing Branch of the Queens Public Library at the intersection of Main Street and Kissena Boulevard, Saint Michael's Church on Union Street between Barclay Avenue and 41st Avenue, the Free

Willeys Point Development

Synagogue of Flushing at the corner of Kissena Boulevard and Sanford Avenue, P.S. 20 at Sanford Avenue and Union Street, and the Flushing Post Office on Main Street between Sanford and Maple Avenues. The Boy's Club of New York is located west of Main Street, at the intersection of Frame Place and 41st Road.

The New York City Department of Environmental Protection (DEP) recently constructed a sewage retention tank at the eastern corner of College Point Boulevard and Fowler Avenue, on top of which is a DPR soccer field.

As stated previously, the LIRR Port Washington Line forms the northern boundary of this subarea, with a station located at Main Street and 41st Avenue. Flushing Municipal Lot No. 3 is adjacent to the LIRR station on 41st Avenue, with approximately 157 parking spaces.

This subarea is bounded on the south by Kissena Corridor West, a 100-acre park that links Flushing Meadows-Corona Park (west of the Van Wyck Expressway) to Kissena Park east of Kissena Boulevard. Kissena Corridor West contains the Queens Botanical Garden, as well as natural areas and recreational amenities.

Flushing Subarea C

This subarea is generally located east of Linden Place, between the Whitestone Expressway and Northern Boulevard, and contains the residential neighborhood surrounding Leavitt Field, a large park.

Residential buildings in this area are a mix of single- and multi-family homes and mid- to high-rise apartment buildings. High-rise apartment buildings are located north of 32nd Avenue. Single- and multi-family homes and some mid-rise apartment buildings are generally located south of 32nd Avenue. Latimer Gardens, a 424-unit NYCHA apartment complex, is located south of 32nd Avenue, adjacent to Leavitt Field. Leavitt Field, an approximately 7.5-acre park bounded by 32nd Avenue, Leavitt Street, and 137th Street, primarily contains active recreational uses, including tennis courts and ballfields.

Neighborhood commercial and office uses are primarily located along Northern Boulevard and Union Street. Commercial uses on Union Street are located on the ground floor with residential units above.

There are numerous community facilities in this area. Educational institutions include Queens Academy High School, P.S. 242, and H.S. 460 (Flushing High School). Several churches are located along Union Street and 35th Avenue. Other community facilities include the Union Plaza Health Care Facility, and Flushing Town Hall, located on Northern Boulevard.

College Point

The College Point subarea is a predominantly industrial area located on the Flushing Bay waterfront, and extends to 28th Avenue to the north and the Whitestone Expressway to the east. This subarea contains heavy industrial and commercial uses located on large lots, and is partially located within the College Point Corporate Park, which covers the area north and east of College Point Boulevard and the Whitestone Expressway. The Corporate Park is described in more detail below under "Public Policy." Several heavy industrial uses located along the waterfront are water-dependent, and use barges to transport materials to and from their facilities.

Large industrial and manufacturing uses in this subarea include Ferraro Brothers Cement, St. Lawrence Cement, and Crystal Windows and Doors, as well as two large municipal facilities that are currently under construction. The new Department of Sanitation of New York (DSNY) North Shore marine transfer station (MTS), part of DSNY's long-term waste export program, is located on Flushing Bay at 31st Avenue. The facility is currently under construction and is expected to be

complete in 2013. The City also is currently constructing a new NYPD academy on the site of the former NYPD tow pound between 28th Avenue and College Point Boulevard. These projects are described in greater detail below in Section D, “Future without the Proposed Project.”

This subarea also includes several large-scale commercial uses. A Home Depot is located on 31st Avenue, west of College Point Boulevard. Several commercial uses are located along the Whitestone Expressway, including a shopping center with a multiplex cinema, Toys ‘R’ Us, an Office Depot, and the Whitestone Executive Plaza, which contains office space and several commercial establishments. Other commercial uses are located along College Point Boulevard and include a Marriott Fairfield Inn hotel, as well as auto-related uses such as towing, car wash, and a truck dealer and repair. In addition, the Williamsburgh Yacht Club is located on Flushing Bay at 28th Avenue.

One large institutional use is located in this area; the Korea World Mission Center, which also houses the Full Gospel Christian School. There are no residential or open spaces in this area.

ZONING

Zoning is a tool for implementing the City’s planning and development objectives by regulating land use, density, and building bulk. Existing zoning and its relationship to land use character are described below. The existing zoning on the project site and in the surrounding study areas is shown in **Table 2-1** and **Figure 2-2**.

Table 2-1
Zoning Districts in Primary and Secondary Study Areas

Zoning District	Maximum FAR ^{1,2}	Uses/Zone Type
Residence Districts		
R3-2	0.5 R plus 0.1 attic allowance ³	General residence district; low-density housing
R4	0.75 R plus 0.15 attic allowance ³	General residence district; low-density housing
R5	1.25 R, 2.0 CF	General residence district; low-density housing
R5A	1.1 R, 2.0 CF	Contextual residence district; low-density housing
R5D	2.0 R, 2.0 CF	Contextual residence district, low to medium-density housing
R6	0.78 to 2.43 R, 3.0 QH, 4.8 CF	General residence district, medium-density housing
R6A	3.0 R, 3.0 CF	Contextual residence district allowing medium-density housing
R6B	2.0 R, 2.0 CF	Contextual residence district, allowing medium-density housing, low-rise buildings with greater lot coverage
R7-1	3.44 R, 4.0 QH, 4.8 CF	General residence district; medium-density housing
Commercial Districts		
C4-2 ⁴	3.4 C, 2.43 R, 4.8 CF	Major commercial centers outside of central business district
C4-3	3.4 C, 2.43 R, 4.8 CF	Major commercial centers outside of central business district
C4-4	3.4 C, 3.44 R, 6.5 CF	Major commercial centers outside of central business district
Manufacturing Districts		
M1-1	1.0 M, 1.0 C, 2.4 CF	Light manufacturing and most commercial uses, located adjacent to low-density residential areas
M1-2	2.0 M, 2.0 C, 4.8 CF	Light manufacturing and most commercial uses, older industrial areas, strict manufacturing performance standards
M2-1	2.0 M, 2.0 C	Medium manufacturing and most commercial uses, moderate manufacturing performance standards
M3-1	2.0 M, 2.0 C	Heavy manufacturing and most commercial uses, minimum manufacturing performance standards
Notes:		
¹ Floor area ratio (FAR) is a measure of density establishing the amount of development allowed in proportion to the base lot area. For example, a lot of 10,000 square feet (sf) with a FAR of 1 has an allowable building area of 10,000 square feet. The same lot with an FAR of 10 has an allowable building area of 100,000 sf.		
² CF=Community Facility, R=Residential, QH=Quality Housing, C=Commercial, M=Manufacturing.		
³ The maximum FAR is increased by the attic allowance which provides up to 20 percent additional FAR for space beneath a pitched roof that has structural headroom of between five and eight feet.		
⁴ Commercial overlay districts including C1-2, C1-4, C2-1, C2-2, and C2-4 are mapped with residential districts (R5 and above) along the study area’s heavily traveled roadways.		
Source: New York City Zoning Resolution.		

Existing Zoning
Figure 2-2

PROJECT SITE

The Special Willets Point District is coterminous with a C4-4 zoning district. The District was created in 2008 to allow for the redevelopment of this portion of the project site consistent with the Willets Point Development Plan.

C4-4 commercial districts are located outside of central business districts and generally serve a larger region than neighborhood shopping areas. Within the District, the zoning allows a range of maximum FARs, as follows: in the area generally west of 127th Street and south of 34th Avenue, a maximum 5 FAR; west of 127th Street and north of 34th Avenue, 3.4 FAR; east of Willets Point Boulevard, 4.0 FAR; north of 34th Avenue and east of 127th Street, 2.0 FAR; and in the triangle formed by 34th Avenue, 127th Street, and Willets Point Boulevard, 3.0 FAR. Throughout the District, the maximum commercial FAR is limited to 2.0.

As defined in the Zoning Resolution, the establishment of the District in 2008 was designed to promote several specific goals:

- Transform Willets Point into a diverse and sustainable community that enhances connections to its surroundings through a unique combination of uses;
- Create a retail and entertainment destination that catalyzes future growth and strengthens Flushing's role as a nexus of economic, social, and cultural activity;
- Encourage a mix of uses that complement sporting venues within Flushing Meadows-Corona Park;
- Maximize utilization of mass transit, reducing the automobile dependency of the redevelopment;
- Create a livable community combining housing, retail, and other uses throughout the District;
- Create a walkable, urban streetscape environment with publicly accessible open spaces;
- Encourage the pedestrian orientation of ground floor uses;
- Build upon the diversity of the Borough of Queens as well as the proximity of regional transportation facilities, including the Van Wyck and Whitestone Expressways, LaGuardia and JFK Airports and the LIRR;
- Provide flexibility of architectural design within limits established to assure adequate access of light and air to the street, and thus to encourage more attractive and economic building forms; and
- Promote the most desirable use of land and building development in accordance with the District Plan and Urban Renewal Plan for Willets Point and thus improve the value of land and buildings and thereby improve the City's tax revenues.

The regulations of the District waive certain C4-4 district requirements and the need for certain CPC and New York City Board of Standards and Appeals (BSA) special permits. To create an appropriate scale and density within the District's surroundings, the District regulates a number of urban design elements, including the number of intersections along 126th Street, building heights and setbacks, street hierarchies, streetscape design, and basic site planning and design provisions.

The Willets West and Roosevelt Avenue areas of the project site are mapped parkland that has been authorized for other uses by statute. A small M1-1 area in the South Lot along Roosevelt Avenue is not part of the project site.

PRIMARY STUDY AREA

The areas north and east of the District within the Willets Point peninsula are zoned R3-2 and M3-1, and the portions of the Flushing Bay waterfront north of the project site are mapped as parkland. Much of the area south of the project site also is mapped as parkland (part of Flushing Meadows-Corona Park); however, the area south of the Roosevelt Avenue portion of the project site containing the LIRR tracks and Corona Rail Yard is zoned M1-1.

R3-2 districts are general residential districts that allow a variety of housing types. R3-2 districts allow a maximum FAR of 0.6, which includes a 0.1 attic allowance. M3 districts allow heavy industrial uses that generate noise, traffic, or pollutants. They are typically located on waterfronts or in industrial sectors, where they can be buffered from residential areas. M3-1 districts allow a maximum FAR of 2.0, and parking is required. The M1-1 district allows light industrial uses that comply with more stringent performance standards, such as warehousing, storage facilities, and auto repair shops. A maximum FAR of 1.0 is permitted in M1-1 districts.

Flushing

The Flushing subarea contains a mix of zoning districts, with manufacturing (M3-1, M2-1, M1-2, and M1-1) and commercial (C4-2) districts located near the Flushing River waterfront, and commercial (C4-3) and residential (R6) districts located farther east.

Downtown Flushing—Subarea A

The Downtown Flushing subarea contains commercial C4-2, C4-3, and C4-4 districts and a residential R6 district. The C4-2 district generally extends west of Main Street to the Flushing River waterfront; this area was rezoned in 1998 from a manufacturing district to encourage residential and commercial development along the waterfront. The zoning also requires new development to provide public access to the waterfront in accordance with a Waterfront Access Plan (WAP). The blocks between Main and Union Streets are generally mapped C4-3, and a C4-4 district is bounded by Union Street, Rosenthal Place, 138th Street and 33rd Avenue. C4 districts are mapped in regional commercial districts and allow medium density commercial development and uses such as specialty and department stores, which serve the needs of a larger area. Both the C4-2 and C4-3 districts allow residential uses at a maximum FAR of 2.43 and commercial uses at a maximum FAR of 3.4. C4-4 districts allow residential at a maximum FAR of 3.4 and commercial uses at a maximum FAR of 3.44.

An R6 district extends east of Union Street between Northern Boulevard and the LIRR right-of-way forming the southern boundary of this subarea. Residential R6 districts are medium-density residential districts which allow a maximum FAR of 2.43. The character of R6 districts typically range from row houses to larger tower developments. Much of the R6 district in this subarea contains either a commercial C1-2 or C2-2 overlay. Commercial overlays within residential districts generally serve the local retail needs of the surrounding neighborhoods. Within the R6 district, both commercial overlays permit commercial uses at an FAR of 2.0.

Just south of Northern Boulevard, close to the Flushing River, are manufacturing M3-1 and M1-1 districts. The characteristics of these districts are described above.

Willels Point Development

Flushing Subarea B

This subarea is generally zoned for manufacturing uses. Zoning districts to the west of College Point Boulevard are predominantly M1-1 and M1-2 with a small enclave zoned M3-1. As described above, M1 districts are for lighter industrial uses, while M3 districts are for heavy industrial uses and contain minimum performance standards. M1-1 districts permit a maximum FAR of 1.0, while M1-2 and M3-1 districts permit a maximum FAR of 2.0. Both zoning districts have parking requirements, which vary depending on the type of use and size of the establishment.

A small portion of this area is within a residential R6 district, with a commercial C2-3 overlay extending along a stretch of College Point Boulevard. The commercial C2-3 overlay mapped in this R6 district allows commercial use at 2.0 FAR.

Flushing Subarea C

This subarea is predominantly zoned M1-1 and M2-1; however, a small area to the north of Northern Boulevard is within a residential R6 district with a C2-2 commercial overlay. The characteristics of these zoning districts are described above.

Corona

The Corona subarea is zoned primarily with medium-density residential districts, including R6, R6A, and R6B, with C2-2 and C2-4 commercial overlays. The R6 district has a C2-4 overlay mapped at the corner of Northern Boulevard and Grand Central Parkway; the R6A district has a C2-4 overlay mapped along Northern Boulevard; and the R6B district has a C2-4 overlay mapped along 108th Street and the north side of Roosevelt Avenue, and a C2-2 overlay mapped along the south side of Roosevelt Avenue. The R6A district extends along portions of Astoria and Northern Boulevards; the R6B district stretches along 108th Street from north of LIRR tracks to 37th Avenue, and along 37th Avenue from 106th to 112th Streets. The area generally south of 37th Avenue is zoned as R5 and R5A districts. Two small areas located north of Northern Boulevard and south of Roosevelt Avenue adjacent to Flushing Meadows-Corona Park are zoned as R4 districts.

The R6A contextual district allows medium-density residential development with a maximum FAR of 3.0. The R6B zoning district allows a maximum FAR of 2.0 and restricts density, limits building heights, and requires minimum setbacks in relation to the building's height, thereby maintaining a contextual residential neighborhood with single and multiple-dwelling homes rising four or five stories in height. R5 districts permit a variety of housing stock, including three-story attached houses and small apartment buildings, but limit development to 1.25 FAR with a maximum building height of 40 feet. The R5A district is a contextual residential district with a maximum FAR of 1.1 that restricts building heights and requires minimum setbacks in relation to the building height, thereby maintaining a contextual residential neighborhood with single-dwelling homes rising no greater than 35 feet in height. R4 zoning districts are similar to the R5 district with respect to multi-family development and front, side, and rear-yard requirements; however, they have a lower maximum FAR of 0.75 (up to 0.9 FAR with a 20 percent increase for an attic allowance), which is generally accommodated in the pitched roof design of homes common to this district.

SECONDARY STUDY AREA

Corona

The Corona subarea is zoned primarily for low- to medium-density residential districts, including R4, R5, R5A, and R6B, with commercial overlay districts along the main thoroughfares, such as Roosevelt Avenue, National Street, 103rd Street, and 104th Street. As with the primary study area, smaller portions of this subarea—generally located south of Roosevelt Avenue and north of Northern Boulevard—are within R4 or R5 districts, which are lower-density residential districts described above. An R6B district with C1-2, C1-4, and C2-2 overlays is mapped in the eastern portion of the area along Roosevelt Avenue, National Street, and 103rd Street.

Flushing

Flushing Subarea B

This subarea is primarily zoned R6, although small areas north of Kissena Boulevard are within C4-2 and R7-1 districts. Within the R6 district, a commercial C1-2 overlay is mapped along Main Street. The C4-2 district, as described above, allows major retail businesses and larger local establishments to exist in a high-density area. The R7-1 district allows residential development similar to R6 districts, although a higher FAR (up to 3.44 FAR) is permitted with less lot coverage.

Flushing Subarea C

This subarea is primarily within a residential R6 district. A commercial C2-2 overlay is mapped within this R6 district along Northern Boulevard to the west of Union Street.

College Point

The College Point portion of the secondary study area is predominantly zoned M1-1 and M2-1.

PUBLIC POLICY

Since World War II, there have been numerous attempts to redevelop Willets Point, which became known over the years for its many auto repair businesses and junkyards, and as an incineration ash disposal site for decades prior. Since 2000, these planning efforts have accelerated. In 2001, the New York City Department of Housing Preservation and Development (HPD) held a design workshop that explored potential redevelopment ideas for Willets Point. The workshop recommended land uses that would reconnect Willets Point with its neighboring communities and attract visitors from nearby attractions and facilities such as Downtown Flushing, Flushing Meadows-Corona Park, Shea Stadium, and hotels servicing nearby LaGuardia and Kennedy Airports.

Around the same time, in 2002, the City created the Downtown Flushing Task Force to undertake a community planning process involving City and State agencies, local and State elected officials, community members, advocacy groups, and local business leaders. The resulting development plan, the Downtown Flushing Development Framework, was completed in May 2004. The Framework identified a set of land use and economic goals to revitalize Downtown Flushing, the Flushing River waterfront, and Willets Point, and to strengthen the area as a regional center, with enhanced connections to neighboring amenities and communities, and is described in more detail below.

Willets Point Development

Additional public policies that apply to either the District or the study areas are also described below.

WILLETS POINT URBAN RENEWAL PLAN

The Willets Point Urban Renewal Plan (URP) was adopted in 2008. The URP defined the boundaries of the District and the area to be redeveloped and established maximum square footage development envelopes, in accordance with the City's redevelopment goals. The overall maximum permitted floor area in the District was defined as 8.94 million square feet of zoning floor area (zsf), with maximum permitted floor areas for residential and commercial uses (5,850,000 zsf of residential use, 3,160,000 zsf of commercial use). The URP, as well as the special district regulations, also requires the creation of a minimum of eight acres of open space in the District and a minimum 650-seat school.

DOWNTOWN FLUSHING DEVELOPMENT FRAMEWORK

The Framework was initiated by the New York City Economic Development Corporation (EDC) and New York City Department of City Planning (DCP), and is a land use planning strategy for the future growth and sustainability of Downtown Flushing, the Flushing River waterfront, and the Willets Point peninsula. It considered opportunities for mixed-use development, improved connections with adjacent regional destinations, enhancements to public open spaces and streetscapes, and transportation and parking strategies.

The Framework looked at the development potential of the Willets Point peninsula, examining the opportunity to create a large-scale economic impact and transform the Flushing area into a regional destination. It also discussed the need to improve the environmental quality of the area. The Framework identified the creation of a long-term redevelopment plan for the Willets Point area as one of the principal implementation goals. Based on an analysis of the area's assets and development constraints, the Framework identified the following land use and economic goals to be achieved through development within Willets Point:

- Create a regional destination that would enhance economic growth in Downtown Flushing and Corona;
- Improve environmental conditions in the District and reflect the sensitive nature of its waterfront setting;
- Create a larger, expanded Flushing core by integrating the two sides of the Flushing River through land use and design;
- Complement the adjacent recreational and sporting facilities;
- Optimize use of the existing highway, public transit, and parking infrastructure to minimize local traffic impacts; and
- Create substantial positive economic value for the City and provide a source of quality jobs for area residents.

The Framework identified ways to renew the central business, residential, and shopping core in Downtown Flushing by enhancing the pedestrian experience and retail options. Specific recommendations included a series of streetscape improvements, façade upgrades, a coordinated marketing program, and improvements to the design of critical gateway intersections connecting Downtown Flushing to the surrounding areas. Other recommendations focused on leveraging

Downtown Flushing's significant transportation assets to enhance mobility, improve the pedestrian environment, and enhance mass transit proximity to the waterfront.

The Framework identified the Flushing River waterfront as the greatest unifying element, with the potential to connect activity at Willets Point to the Downtown Flushing area, and envisioned the waterfront area as containing a combination of open space and mixed-use development that would attract residents and visitors to the waterfront. The Framework set forth a number of recommendations for the waterfront area, including: improving the environmental quality of the river and surrounding wetlands; facilitating the creation of an esplanade along the eastern shore of the Flushing River; introducing a new community open space at the northern anchor of the esplanade; and improving access to the waterfront and creating a continuous open space system around the Flushing River.

PLANYC 2030

Released by the City in April 2007 and updated in 2011, this 128-point plan was prepared to create an environmentally sustainable city over the next two decades. PlaNYC focuses on the many facets of New York's environment—its transportation network, housing stock, land and park system, energy network, water supply, and air quality—and sets a course to achieve 10 goals to create a more sustainable New York by the year 2030. Specific goals of the plan include:

- Create enough housing for almost a million more people, and find ways to make housing more affordable;
- Ensure that every New Yorker lives within a 10-minute walk of a park;
- Clean up all contaminated land in New York City;
- Improve the quality of New York City's waterways to increase opportunities for recreation and restore coastal ecosystems;
- Ensure the high quality and reliability of New York City's water supply system;
- Expand sustainable transportation choices and ensure the reliability and high quality of our transportation network;
- Achieve the cleanest air quality of any big city in America;
- Divert 75 percent of our solid waste from landfills;
- Reduce greenhouse gas emissions by more than 30 percent; and
- Increase the resilience of our communities, natural systems, and infrastructure to climate risks.

FLUSHING MEADOWS-CORONA PARK STRATEGIC FRAMEWORK PLAN

The Flushing Meadows-Corona Park Strategic Framework Plan, prepared in 2007, proposes a series of changes and updates to the park with the goal of increasing its functionality and sustainability.

The plan is organized around the concept of remaking Flushing Meadows-Corona Park into "the park of the future," reclaiming the forward-looking heritage of the 1939 and 1964 World's Fairs for which the park was built. The plan includes three broad goals:

Willeys Point Development

- Re-envision the World's Fair Core, including restoration of landmark structures, daylighting of the Flushing River, and creation of more green space, topography, and a new festival gathering space;
- Reconfigure and restore lakes in the park, to improve their utility as natural and recreational resources, create a more diverse ecology, and add additional parkland; and
- Reconnect the park to the neighborhood and city by creating better access and more logical activity corridors within the park, as well as improving accessibility from surrounding neighborhoods and rationalizing parking for visitors from farther afield. This proposal also includes the establishment of a bike-sharing system with the park.

Additional objectives of the plan include reducing runoff, energy use, and impervious coverage in the park; establishing the park as a center for cultural activities; and finding better uses for underutilized structures such as the New York State Pavilion.

The plan also suggests the creation of a transportation management association to coordinate large events (such as Met games, the US Open, and cultural festivals) and associated transportation and parking strategies; conformance with PlaNYC's standards for green parking lots, including for the CitiField parking areas; and improving of links between the marina area and the park's historic World's Fair core. For the CitiField parking area itself, it suggests that a parking garage could be developed, leaving space for additional green areas. No suggestions are made for the South Lot or Lot D.

COLLEGE POINT CORPORATE PARK

A portion of the College Point subarea lies within the College Point Corporate Park, a 550-acre corporate park formed in 1969 on land acquired through eminent domain under the College Point II Urban Renewal Plan. The corporate park is currently managed by EDC, which disposes the land to various developers. All property disposition in the park includes covenants that restrict land use, guide future design, and require contribution to an improvement fund. The park contains approximately 200 businesses and employs around 6,000 people. Large industrial businesses include the New York Times printing and distribution plant; Crystal Windows, a manufacturer of windows and doors; Ares Printing and Packaging, a printing and distribution company; Graphic Communication Center, another printing and distribution company; and the North American headquarters for Skanska (a Swedish construction company). There are also several big box retailers in the park, including a Target Greatland, BJ's Warehouse, TJ Maxx, and Circuit City. Additional retailers in the park include Old Navy, Staples, Toys 'R' Us, Babies 'R' Us, a Walbaums supermarket (including a Walbaums corporate training center), Boulder Creek Steakhouse, and a multiplex cinema. The former Flushing Airport site, which is within the corporate park, comprises 16 percent of developable land within the park.

WATERFRONT REVITALIZATION PLAN

As shown on **Figure 2-3**, the project site and portions of the study area are within the City's designated Coastal Zone. Therefore, an assessment of the consistency of the proposed project with the City's Waterfront Revitalization Program (WRP) is warranted. This assessment is provided below under Section F, "Waterfront Revitalization Program."

Figure 2-3

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

LAND USE

PROJECT SITE

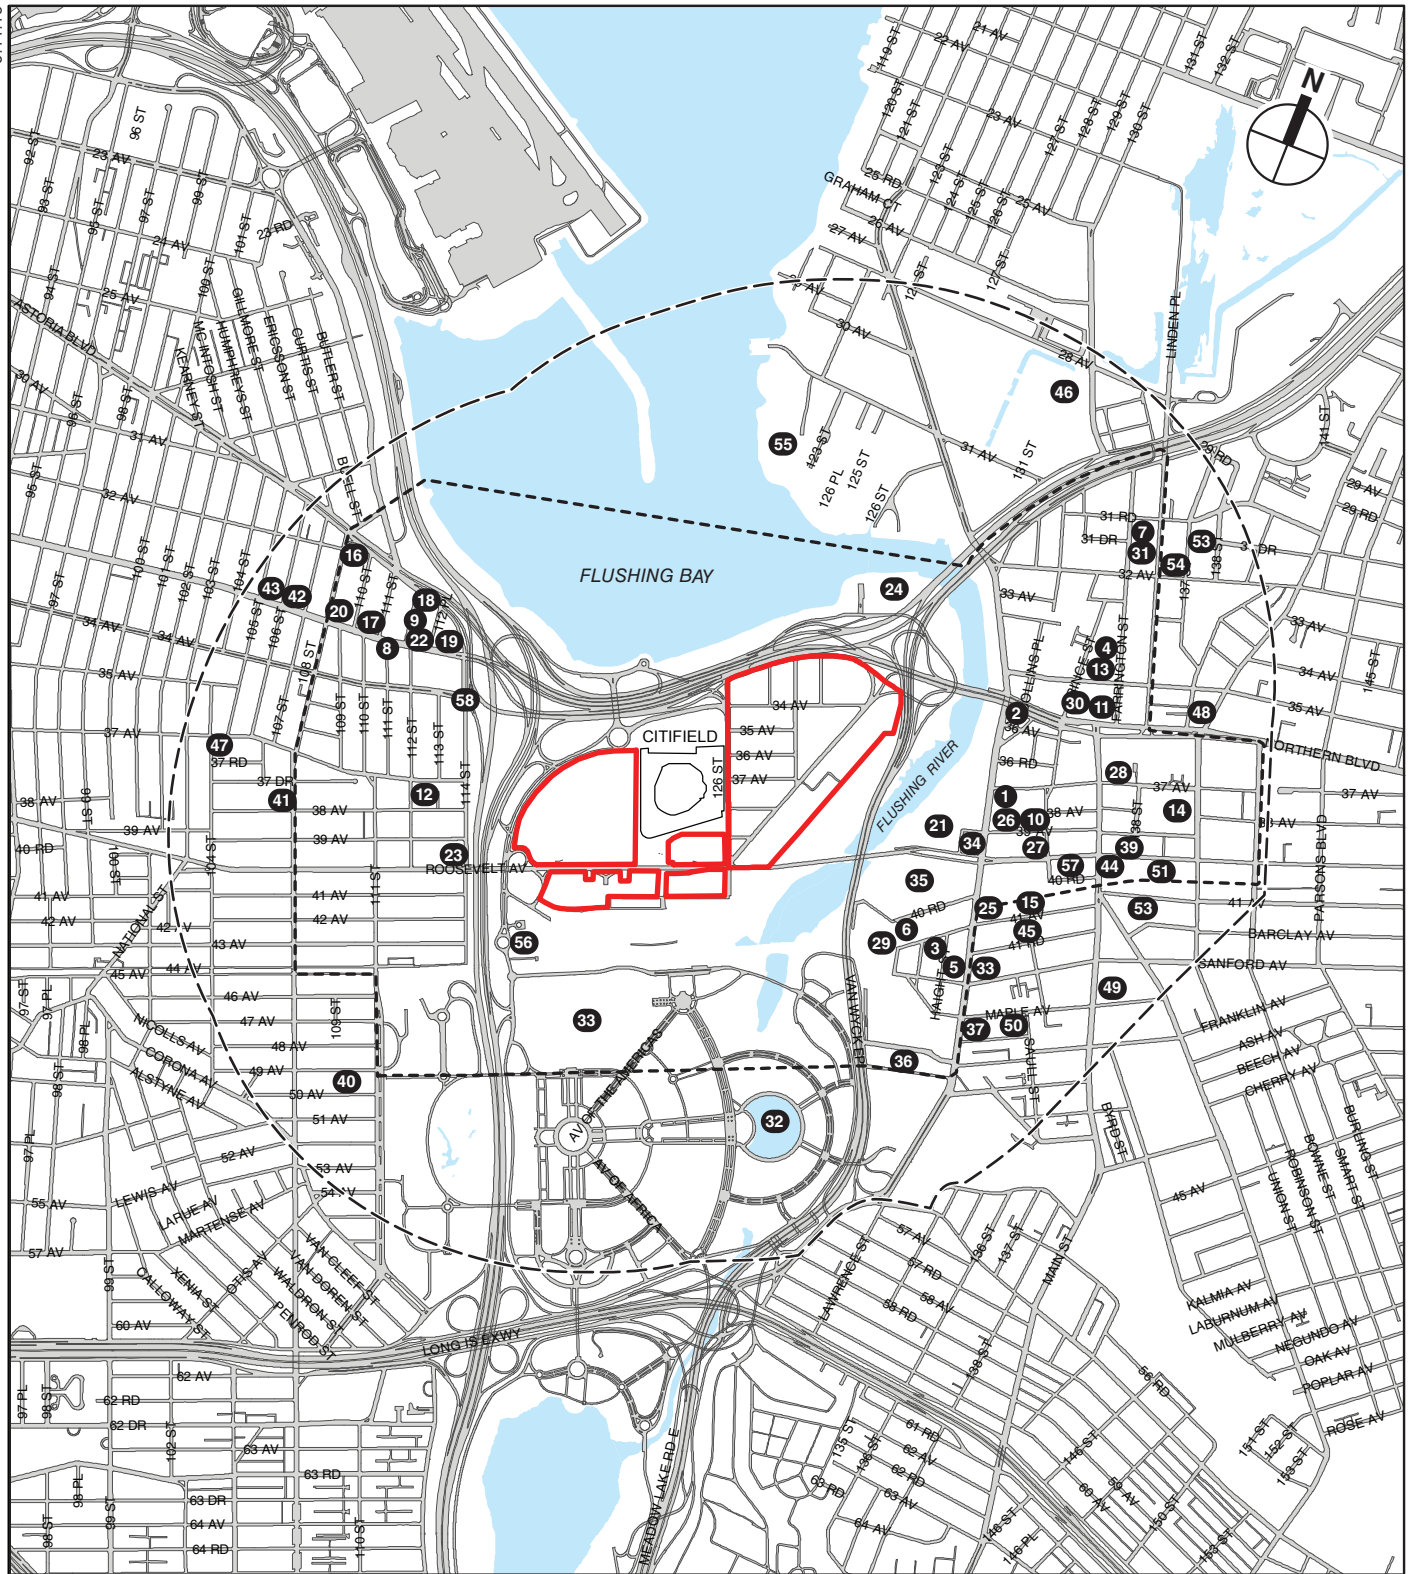

As described in Chapter 1, “Project Description,” for the purposes of a conservative analysis, the RWCDs for this EIS assumes that no changes to land use occur on the project site for the three analysis years: 2018, 2028, and 2032. Without the proposed project, it is expected that the District would continue to have the existing industrial and auto-related uses and would continue to be isolated from surrounding neighborhoods, and that the Willets West and Roosevelt Avenue portions of the project site would continue to serve the parking needs of CitiField.

PRIMARY STUDY AREA

In the future without the proposed project, the existing uses in the remainder of the Willets Point peninsula, including the undeveloped MTA property to the east of the District, also are expected to remain unchanged.

A substantial amount of new development is either under construction or planned within the remainder of the primary study area, including several large-scale mixed-use redevelopment projects, primarily located in Downtown Flushing, and numerous residential developments in the Corona and greater Flushing areas. As shown in **Table 2-2** and mapped in **Figure 2-4**, approximately 39 development projects are either under construction or proposed for the primary study area. All but two of these projects are anticipated to be complete by 2018. The USTA NTC Strategic Vision project is anticipated to be complete by 2019. A portion of the Flushing Commons project is anticipated to be complete by 2018; the remainder of the project will be complete by 2028. No other development projects have been identified for completion between 2018 and 2032 in the primary study area.

In recent years, there has been increased interest in the development of mixed-use projects along the Flushing River waterfront. Across the Flushing River from the District, the second phase of Sky View Parc will add 600 residential units to this mixed-use development by 2018. Another large mixed-use development, River Park Place, is planned on the east side of the Flushing River waterfront just north of Roosevelt Avenue, and has been assumed to be completed in 2018. Current plans for this development include 475 residential units, 251,000 sf of office use, 10,200 sf of retail use, 1,500 sf of community facility use, and either a 175-room hotel or an additional 96,500 sf of office use. This project will also include a waterfront esplanade, as required by the WAP. It is expected that the trend of new mixed-use development along the waterfront will continue over the long term without the proposed project, following current development projects and alongside other initiatives proposed as part of the Framework to improve connections between Downtown Flushing and the Flushing waterfront.

Notes: DU = dwelling unit * Projects without specific information regarding their build years are assumed to be developed by 2018 (the first analysis year for the proposed project). ¹ This is a proposal that will require discretionary land use approvals; however, because it is located in close proximity to the project site, it has been included as a No Action development for conservative impact analysis. Sources: AKRF, Inc., New York City Department of City Planning, New York City Department of Buildings, and the New York City Economic Development Corporation.			

Willels Point Development

A planning effort is being undertaken by the Flushing Willels Corona Local Development Corporation (FWCLDC), in consultation with DCP, with funding from the New York State Department of State (NYSDOS) under the Brownfield Opportunity Areas (BOA) Program. This Flushing BOA Plan encompasses approximately 60 acres on the Flushing River waterfront, bounded by Northern Boulevard to the north, Roosevelt Avenue to the south, Prince Street to the east, and the Van Wyck Expressway to the west. Begun in spring 2011, this planning initiative involved a public outreach and participation program including a series of stakeholder and community meetings and visioning sessions. The study seeks to identify land use and zoning recommendations within the Flushing BOA to allow the potential for greater residential density and contextual design in order to create a more mixed-use character, as well as improved public access along the waterfront than currently allowed under the existing C4-2/M1-1 zoning districts. The Flushing BOA Plan builds off the 2004 Downtown Flushing Development Framework. Consistent with the Framework's goals, the Flushing BOA Plan intends to update and improve on the 1998 rezoning enacted in the area as a result of the 1993 Downtown Flushing Waterfront Access Plan. However, this planning effort is still in development with no discrete program or set implementation time table. The recommendations, which have not been developed yet for this Flushing BOA Study, would require future discretionary land use approvals and public review. Ongoing consultation with DCP, other key agencies, stakeholders, and the community at-large will continue through 2013.

Several large-scale, mixed-use developments are either under construction or planned for Downtown Flushing. In the heart of Downtown Flushing, Flushing Commons, a mixed-use project proposed for development on Municipal Lot No. 1, is expected to contain approximately 620 residential units, 275,000 sf of retail use, 110,000 sf of office use, 98,000 sf of community facility use, 1,600 parking spaces, and either 250 hotel rooms or an additional 124,000 sf of office use, as well as 1.5 acres of passive open space. The former Caldor building at Roosevelt Avenue and Main Street will be redeveloped with 155,000 sf of retail use.

There are also several mixed-use developments planned or under construction in Flushing north of Northern Boulevard. These include a mixed-use development on 35th Avenue with 84 residential units, community facility and retail use, and approximately 220 parking spaces and a mixed-use development on Northern Boulevard with 28 residential units, community facility and retail use, and approximately 45 parking spaces. In addition, the redevelopment of RKO Keith's Theater (a 1920s movie house) to include 357 residential units, 17,000 sf of retail use, 12,500 sf of community facility use, and approximately 385 parking spaces is anticipated by 2018.

Eight additional projects are projected to be developed in the area between Northern and Astoria Boulevards by 2018, as a result of the recent rezoning of Corona. If developed, these large mixed-use projects would bring approximately 320 new residential units to the area, along with approximately 98,000 sf of retail use, approximately 61,000 sf of community facility use, a hotel, and a public school.

The City, through DPR, is currently in discussions with a private entity for a lease covering the construction and operation of a new stadium for professional soccer purposes in an approximately 13-acre area within the northern portion of Flushing Meadows-Corona Park south of Roosevelt Avenue and eastward of the USTA NTC. As currently contemplated, a 25,000-seat stadium (with the ability to be expanded to 35,000 seats) would be constructed by 2016 on the present site of the Fountain of the Planets and land surrounding the fountain. In addition to the fountain, the stadium would displace four existing soccer fields, a basketball court, landscaped areas, and pathways, which would be relocated to other locations within the park. Both New

York State parkland alienation legislation and Land and Water Conservation Fund Act considerations will require the provision of replacement park land. Although the project requires city, state, and federal approvals and public review, the project is being considered as part of the No Action condition for the proposed project, as it is currently under consideration by the City and is in proximity of the proposed project.

Elsewhere in Flushing Meadows-Corona Park, ongoing capital improvement projects are being carried out by DPR to provide for up to date recreational facilities. One soccer field is currently being renovated and an additional two soccer fields will be renovated by 2019. In addition, capital funds have been allocated to repair a fourth soccer field and create volleyball courts located on the eastern edge of the park and south of Fountain of the Planets. Construction of an annex to the Olmsted Center is currently underway and is anticipated for completion in 2013. Although it is currently unfunded, DPR has identified as a priority project within Flushing Meadows-Corona Park the repair of the tide gates so as to improve drainage flow that affects existing park facilities. Some City capital funding has been allocated for streetscape improvements on Roosevelt Avenue west into Corona; however, there are no specific designs or timeline for implementation for this proposal.

SECONDARY STUDY AREA

Approximately 19 development projects are proposed for the secondary study area by 2018; no other development projects have been identified for completion between 2018 and 2032 in the secondary study area. Several new multi-family and mid-rise and residential apartment buildings are currently under construction in the Corona subarea. Several new residential buildings within the area between 37th Avenue and the LIRR tracks will bring a total of 73 new units to the area. Two mixed-use buildings and one commercial building are also projected to be developed on Northern Boulevard by 2018.

In the residential area south of Roosevelt Avenue in Flushing, several residential projects are either planned or under construction in this area that will collectively introduce approximately 193 new residential units. In addition, a new 425-seat primary school is being constructed at Franklin and Golden Avenues.

North of Northern Boulevard in Flushing, several residential projects are planned or are under construction, which together will introduce approximately 34 new units to the area. A church at Parsons Boulevard and 32nd Avenue is also projected to be completed by 2018, as well as an approximately 13,500 sf community facility at Parsons Avenue and 34th Avenues.

Two major projects are expected to be completed in the College Point subarea in the future without the proposed project. These include the North Shore MTS on Flushing Creek at 31st Street, and the new NYPD academy on 31st Avenue at College Point Boulevard. The converted MTS is included in DSNY's Solid Waste Management Plan for long-term waste export, and would receive and containerize waste from Queens Community Districts 7 through 14, exporting waste by barge. The MTS facility is expected to begin operating in 2013, once the required permits are granted by the New York State Department of Environmental Conservation (NYSDEC). The new NYPD academy, which is planned to be constructed by 2018, will include a 30-acre campus with 250 classrooms, 250 beds for visiting law enforcement agencies, firing ranges, indoor and outdoor tracks, and areas for simulated training activities.

ZONING

In the future without the proposed project, the Flushing Meadows East Rezoning is expected to occur within the primary study area.¹ The rezoning is anticipated to result in the construction of up to 378 dwelling units and approximately 148,100 square feet of retail space.

PUBLIC POLICY

In the future without the proposed project, no new policies are expected that would affect the project site or the primary and secondary study areas. Without the proposed project, an essential component of the Downtown Flushing Development Framework—i.e., the redevelopment of the Willets Point peninsula—would not proceed, and many of the Framework’s goals, which focus on facilitating future growth and sustainability of the area through the redevelopment of Willets Point, would not be achieved. It is expected that the City would continue to explore opportunities to advance the other components of the Framework, such as opportunities for mixed-use development in Downtown Flushing, enhancements to public open spaces and streetscapes, improved connections between Downtown Flushing and the Flushing waterfront, and transportation and parking strategies. Specific objectives outlined in the Framework include upgrading streetscapes between the Downtown Flushing core and the waterfront, and improving pedestrian conditions along College Point Boulevard. However, goals such as improving environmental conditions in the District and enhancing adjacent regional destinations would not likely be achieved in the future without the proposed project. Additionally, as Willets West, the South Lot, Lot D, and Lot B would remain surface parking areas, the goals outlined in the Framework, such as creating regional destinations that would enhance economic growth in Downtown Flushing and Corona, also are unlikely to be achieved.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

By 2032, the proposed project would incorporate a development substantially similar to what was anticipated and analyzed in the 2008 FGEIS and subsequent technical memoranda, as well as a major entertainment/retail development and several parking garages adjacent to CitiField. Changes to the RWCDs analyzed here versus that analyzed in the 2008 FGEIS include an increase in the overall amount of retail development from 1.7 million square feet to 2.65 million square feet. This increase results from the development of the 1.4 million square foot (1 million leasable square foot) development at Willets West combined with a concurrent reduction in the overall amount of retail in the District from 1.7 million square feet to 1.25 million square feet. The Supplemental EIS (SEIS) also assumes 5.85 million square feet of residential development to match the highest amount of residential analyzed in the 2008 FGEIS (in the No Convention Center Scenario), and a 230,000-square-foot school rather than the 2008 FGEIS’s 130,000-square-foot school. The project is anticipated to proceed in three phases with build years occurring in 2018, 2028, and 2032.

¹ A DCP-initiated rezoning study of East Elmhurst is currently underway, of which Block 1679 is within the primary study area and all or portions of Blocks 1657, Blocks 1657, 1671, 1672, 1675, 1676, 1677, 1691, 1692, 1693, and 1694 are within the secondary study area. Lower-density zoning changes are being considered for most of the rezoning area, however, an upzoning may be proposed for some areas. Additional information on this potential rezoning will be included as it becomes available.

Consistent with the 2008 FGEIS and subsequent technical memoranda, the RWCDs also includes a conceptual development program for Lot B, to be completed by 2032: 184,500 sf of retail use and 280,000 sf of commercial use.

This section evaluates the potential for the RWCDs to result in significant adverse land use, zoning, and public policy impacts compared with the future without the proposed condition described above.

LAND USE

PROJECT SITE

The RWCDs would develop up to 10.34 million zsf in new buildings on the project site, which would include residential, retail, office, hotel, community facility, public school, parking, and convention center uses, as well as publicly-accessible open space. The project would include environmental remediation of the project site; installation of new sanitary and storm sewer lines; and grading and elevation of the District above the 100-year floodplain. It also would result in the displacement of existing uses on the project site.

Phase 1A

The first phase of the project, anticipated to be complete by 2018, would commence with the remediation and development of an approximately 23-acre portion of the District and the development of Willets West on the existing parking lot west of CitiField. Upon completion of the environmental remediation for the District, an approximately 200-room hotel and approximately 30,000 square feet of retail space would be constructed above the floodplain along the east side of 126th Street, with a 20-foot-wide public esplanade. These uses are consistent with existing approvals made for the District in 2008. An approximately 2,825-space interim surface parking area would be developed within the District east of the retail and hotel uses. A majority of this parking area would be converted to active recreational use a minimum of 6 months per year.

The Willets West portion of the project site would be developed with an entertainment and retail center of approximately 1.4 million gross square feet (1 million leasable square foot). The complex could include over 200 retail stores, including anchor and “mini” anchor retailers, as well as movie theaters, restaurant and food hall spaces, and entertainment venues. Surface parking and a parking structure also would be developed in this portion of the project site, including 2,500 new spaces for the entertainment/retail center and 400 spaces of replacement parking for use by the Mets. In addition, a six-story structured parking facility with approximately 1,800 parking spaces would be constructed on the western portion of the South Lot, replacing approximately 640 of the existing surface parking spaces on that portion of the lot.

The redevelopment of the District and the development of the Willets West entertainment and retail complex in Phase 1A would dramatically change land uses on the project site, replacing a surface parking field and low-density auto-related, manufacturing, warehousing and distribution uses with new retail, hotel, entertainment, and recreational uses. The new uses at Willets West would complement existing retail and entertainment uses around the project site in the Flushing and Corona neighborhoods, as well as the CitiField and USTA NTC uses within Flushing Meadows-Corona Park. While the undeveloped portion of the District would continue to contain auto-related and industrial uses, the proposed surface parking use is not considered to be

Willeys Point Development

incompatible with such uses. The proposed surface parking would support the Willets West entertainment and retail complex and the retail and hotel development along 126th Street, when not in use for CitiField game parking or active recreation. The active recreational uses also would be compatible with the recreational uses in Flushing Meadows-Corona Park. During the times of year when the recreational uses would be operational, they would differ from the uses in the undeveloped portion of the District; however, the majority of the recreational uses would be clustered together on a portion of the District that would not have through-access to the remaining portions. This is anticipated to provide a degree of visual and physical separation of the uses between the undeveloped and redeveloped portions of the District.

It is anticipated that the Willets West development, by building a critical mass of uses, would create a new destination that would serve as a catalyst for the subsequent build-out of the District. As described in Chapter 1, "Project Description," this entertainment and retail center would allow for more comprehensive transit-oriented development around the Mets/Willeys Point stops on the No. 7 train and LIRR and support the economic development of the area.

Therefore, there would be no significant adverse impacts to land uses on the project site as a result of the proposed project's first phase.

Phase 1B

In Phase 1B, anticipated to be complete by 2028, the interim surface parking lot/recreational space created during Phase 1A within the District would be developed into a new neighborhood. The program for this development would be consistent with the District's zoning and would include approximately 4.23 million square feet of development, including residential, retail, additional hotel, office, parking, and community facility uses, in addition to a public school and approximately six acres of open space. This development is anticipated to be developed block by block, substantially as envisioned in the Willets Point Development Plan. In addition, two six-level structured parking facilities would be constructed on the eastern portion of the South Lot and Lot D to replace the CitiField parking spaces located within the District in Phase 1A. The 75 accessory parking spaces created in Phase 1A for the hotel would remain in the District and be incorporated into a garage portion of an enlarged hotel block.

Within the District, the previously approved special district regulations would determine the placement of uses, building heights and setbacks, street hierarchies, maximum block dimensions, streetscape design, and basic site planning and design provisions within the District, as well as the general layout of the principal streets, thereby establishing the basic form of the District, encouraging a pedestrian-friendly neighborhood environment, and ensuring that the new uses in the District are integrated into a cohesive site design. The land uses proposed in Phase 1B would be consistent with and support the uses developed in the Willets West portion of the project site in Phase 1A.

As in Phase 1A, the uses in the redeveloped portion of the District in Phase 1B would differ from those in the undeveloped portion of the District, which would continue to contain primarily auto-related uses. The buffer area between the developed and undeveloped portions of the District analyzed in the Staged Acquisition Alternative of the 2008 FGEIS and subsequent technical memoranda is not part of the proposed project. However, because streets in the undeveloped portion of the District would generally remain at their existing grade through Phase 1B, streets in the redeveloped portion of the District would be graded to slope down to the existing streets to the east, forming a physical barrier between the Phase 1B development and existing uses in the undeveloped portion of the District. There is anticipated to be some

regrading in the undeveloped portion of the District to meet the grade of the new Van Wyck Expressway access ramps, which would be operational prior to the occupancy of the Phase 1B buildings. Any grade changes that would exist in Phase 1B would serve to provide a degree of visual and physical separation of the uses between the undeveloped and redeveloped portions of the District. In addition, although there is no designated buffer area between the Phase 1B development and adjacent auto-related uses, the open space areas provided east of Willets Point Boulevard and north of 35th Avenue would serve to buffer the residential and community facility uses from nearby auto-related uses. Heavier industrial-related uses associated with the two waste-transfer stations in the District also would not be located near the developed portion of the District. The previously approved rezoning of the District to C4-4 would further ensure that no new industrial or auto-related uses would be established in the undeveloped portion of the District during the four year period between Phase 1B and Phase 2. Finally, as described in more detail below, the placement of high-density mixed-use or residential districts adjacent to auto-related and light-manufacturing districts is not uncommon in the City. Therefore, there would be no significant adverse impacts to land use as a result of the proposed project's second phase.

Phase 2

In Phase 2, anticipated to be complete by 2032, the remainder of the District would be built out consistent with the area's previously approved zoning and substantially as anticipated in the 2008 FGEIS. Upon completion of Phase 2, the District is anticipated to include: up to 5.85 million gross square feet (approximately 5,850 units) of residential use; up to 1.25 million gsf of retail; approximately 500,000 gsf of office; up to 400,000 gsf of convention center use; up to 560,000 gsf of hotel use (approximately 700 rooms); up to 150,000 gsf of community facility use; approximately 230,000 gsf of public school use; and a minimum of 8 acres of publicly accessible open space. The number of proposed parking spaces would be determined based on project-generated demand, but is anticipated to be no more than the 6,700 spaces identified in the 2008 FGEIS.

As described above, for the RWCDs, it also is anticipated that by 2032 Lot B could be developed with a one-story retail structure and a 10-story office building containing 184,500 sf of retail use and 280,000 sf of commercial use with associated surface and structured parking.

Overall, consistent with the conclusions of the 2008 FGEIS, the RWCDs would dramatically change land uses on the project site, replacing predominantly low-density auto-related, manufacturing, warehousing and distribution uses with a new mixed-use neighborhood in the District, and replacing surface parking areas adjacent to CitiField with a new entertainment and retail development and parking garages to serve Mets patrons. Of the approximately 5,850 residential units proposed to be completed by Phase 2, thirty-five percent (approximately 2,048 units, or approximately 2,048,000 zsf) would be affordable housing units. The redevelopment of the District, the development of the Willets West entertainment and retail complex, and the potential future office and retail development on Lot B would create a sustainable, dynamic community around CitiField by integrating regional attractions—such as the convention center, entertainment, and destination retail uses—and residential, community facility, and other uses within a network of pedestrian-scaled streetscapes.

Consistent with the conclusions of the 2008 FGEIS, while the RWCDs would result in a significant change to land use, the effects of this change would not be adverse. The proposed convention center, retail, entertainment, and commercial uses would enhance Flushing and Corona's roles as regional economic centers, and would attract visitors to the area. The RWCDs

Willets Point Development

would create pedestrian-oriented developments on either side of CitiField, creating a dynamic new mixed-use neighborhood with pedestrian-scaled streetscapes and new entertainment and retail attractions and amenities to integrate this area with uses in neighboring Flushing and Corona, thus improving the quality of life for area residents and visitors. The proposed parking facilities on the South Lot and Lot D would serve to support this new regional destination. The anticipated development of Lot B with retail and office uses would further enhance the land uses proposed on the project site as well as the overall economic development of the area.

PRIMARY STUDY AREA

Land use issues associated with the RWCDS focus on the compatibility of the new land uses with those that are already established and anticipated to occur in the primary study area in the future without the proposed project; the effect that introducing dense development on the project site would have on adjacent land use patterns; and the likelihood for the new land uses to generate land use change in the study area.

Land Use Compatibility

Phase 1A

The retail, entertainment, hotel, and parking uses that would be developed in Willets West, the District, and the South Lot in Phase 1A are prevalent throughout the primary study area, particularly within the dense commercial center of Downtown Flushing and the Roosevelt Avenue and Northern Boulevard commercial corridors in Corona. The proposed land uses would be more compatible with these adjacent neighborhoods than the existing industrial and auto-related uses, and would reflect the new trend of higher-density, mixed-use development that is occurring in Downtown Flushing, on the Flushing River waterfront, and along Astoria Boulevard.

Although the entertainment and retail uses proposed for the Willets West portion of the project would not be consistent with some passive park uses in the surrounding area, the entertainment and retail uses would complement the adjacent CitiField stadium and other cultural facilities located within the boundaries of Flushing Meadows-Corona Park, providing restaurants and other amenities to support these adjacent uses. Furthermore, the closest passive open spaces within the Flushing Meadows-Corona Park are located approximately one-quarter of a mile south of Willets West, creating a substantial buffer between the two uses. Additionally, as Willets West would attract more visitors to the area, it is likely that a portion of these visitors would also engage in recreational activities in the Flushing Meadows-Corona Park and Flushing Bay Promenade. The entertainment and retail uses proposed for Willets West in Phase 1A would also be compatible with commercial and retail uses in the Corona area and would enhance the economic development of both Corona and Downtown Flushing.

It is expected that the MTA property adjacent to the District would continue to be undeveloped in 2018, as well as 2028 and 2032, and would contain industrial uses that are the same as or similar to the construction and demolition debris recycling operation that exists there today. Although the recreational uses to be developed in the District would not be compatible with the industrial activities permitted on the nearby MTA property, this industrial use is not expected to result in a significant land use impact on the District due to the limited times during which the two uses would be proximate. For the remainder of the year—during the period in which the Phase 1A uses are active within the District, before construction of Phase 1B commences—the surface parking uses to be developed in this area of the District would be compatible with the uses permitted on the MTA property. Furthermore, the recreational uses proposed in the District

are compatible with the portions of the Flushing Meadows-Corona Park located in the primary study area.

Although the uses proposed for the District in Phase 1A would not be consistent with the industrial uses currently located along the waterfront to the northeast, these uses are separated from the District by the Whitestone Expressway and Northern Boulevard, as well as the Flushing River, and therefore would not result in significant adverse land use impacts on the District. The proposed uses within the District in Phase 1A also would not interfere with the active industrial waterfront uses—including barge operations—in the Flushing River and Flushing Bay.

Phase 1B

While the residential, school, commercial office, and community facility uses to be developed in the District in Phase 1B would not be compatible with the industrial activities permitted on the nearby MTA property, the proximity of these uses is not expected to result in a significant adverse land use impact. The placement of high-density mixed-use or residential districts adjacent to heavy manufacturing districts is not uncommon in the City. Other City-sponsored initiatives, such as the rezoning of West Chelsea in Manhattan and Greenpoint/Williamsburg in Brooklyn, have resulted in new higher-density residential districts adjacent to older heavy manufacturing districts. These efforts reflect the City's desire to respond to documented land use trends and to facilitate redevelopment of underutilized properties on the waterfront with new mixed-use development. Furthermore, the District's regulations require the development of an eastern perimeter street, as well as a landscaped open space between 8 and 15 feet wide, which would provide a buffer between the redeveloped District and the adjacent MTA property.

The open space use proposed in Phase 1B would be compatible with the commercial, recreational, and open space uses located in the primary study area, including CitiField, Flushing Meadows-Corona Park, and the Flushing Bay Promenade. The structured parking facilities proposed to be constructed on South Lot and Lot D also would be compatible with parking uses in Downtown Flushing and the portions of Corona in the primary study area, as well as at the adjacent Casey Stengel Bus Depot.

Similar to Phase 1A, the uses proposed for the District in Phase 1B would not be consistent with the industrial uses currently located along the waterfront to the northeast. However, these uses are separated from the District by the Whitestone Expressway and Northern Boulevard, as well as the Flushing River, and therefore would not result in significant adverse land use impacts on the District. The proposed uses within the District in Phase 1B also would not interfere with the active industrial waterfront uses—including barge operations—in the Flushing River and Flushing Bay. Additionally, the uses proposed within the District in Phase 1B would be consistent with ongoing land use and development trends occurring along the Flushing River waterfront, including higher-density and mixed-use development.

Phase 2

As with Phase 1B, the residential, school, hotel, office, and community facility uses to be developed in the District in Phase 2 would not be compatible with the industrial activities permitted on the nearby MTA property. However, as noted above, the District's regulations require the development of an eastern perimeter street, as well as a landscaped open space between 8 and 15 feet wide, which would provide a buffer between the redeveloped District and the adjacent MTA property. Therefore, the industrial use is not expected to result in a significant adverse land use impact on the District.

Willets Point Development

The proposed convention center use that would be developed in Phase 2 is not common in the primary and secondary study areas; a convention center, by its nature, is singular, and there are few such facilities in the region. However, the proposed convention center use would be located in close proximity to LaGuardia airport, and would be compatible with the prevailing land uses in Downtown Flushing and parts of Corona—commercial office and retail—as well as recreational and cultural uses in Flushing Meadows-Corona Park.

As with Phase 1A and 1B, the uses proposed for the District in Phase 2 would not be consistent with the industrial uses currently located along the waterfront to the northeast. Again, these uses are separated from the District by the Whitestone Expressway and Northern Boulevard, as well as the Flushing River, and therefore would not result in significant adverse land use impacts on the District. The uses proposed in Phase 2 also would not interfere with the active industrial waterfront uses—including barge operations—in the Flushing River and Flushing Bay. Additionally, the proposed uses within the District in Phase 2 would be consistent with ongoing land use and development trends occurring along the Flushing River waterfront, including higher-density and mixed-use development.

The anticipated development of Lot B with retail and office uses by 2032 also would be compatible with existing retail and office uses in Flushing and Corona. Overall, the RWCDs would not result in significant adverse land use compatibility impacts in the primary study area.

Land Use Density

As described above, the RWCDs would transform the underutilized area within the District and surface parking lots within the Willets West and Roosevelt Avenue portions of the project site into a new, higher-density, mixed-use neighborhood. Given existing land use patterns and zoning regulations in the surrounding area, however, it is unlikely that the RWCDs would alter land use patterns in the primary study area in 2018, 2028, or 2032.

Phase 1A

The presence of an active, retail and entertainment center in Willets West, in addition to the hotel and retail development in the District and structured parking facility on the South Lot, would increase land use density in the primary study area. However, such a change to uses on underutilized sites would not constitute an adverse impact on land use density in the study area, because the potential new uses—including retail, entertainment, and hotel uses—would be compatible with other uses in the area and would conform to existing zoning and public land use policies, including the Downtown Flushing Development Framework. Although the proposed Willets West structure and South Lot parking facility could be taller than the low-rise buildings located in the Corona portion of the primary study area, these structures would be separated from the Corona subarea by Grand Central Parkway and would not interfere with the residential and commercial uses in Corona.

Phase 1B

The presence of an active, mixed-use development in the District—including residential, retail, hotel, school, and community facility uses—would further increase land use density in the study area. However, this development would be compatible with existing land use densities in the primary study area, as well as recent development on the western bank of the Flushing River, much of which has been rezoned to allow higher-density, mixed-use waterfront development. Therefore, the development of underutilized sites in the District as well as South Lot and Lot D would not constitute an adverse impact on land use densities in the study area, because the

potential new uses would reflect a continuation of an existing trend. As with Phase 1A, the proposed uses also would conform to existing zoning and public land use policies.

Phase 2

The development proposed in Phase 2 and the potential retail and office building that could be constructed on Lot B would increase the density of the District as well as along Roosevelt Avenue. However, as with Phase 1B, this development would be compatible with existing land use densities in the primary study area. Furthermore, the proposed dense development would be more compatible with the density of surrounding uses than the existing auto-related and industrial uses in the District and the CitiField surface parking lots, and would serve to further integrate the area around CitiField with development along Northern Boulevard, as well as the rapidly expanding Downtown Flushing area. In addition, the density of the RWCDs is consistent with existing land use patterns in Downtown Flushing, as well as new development that is under construction or planned in the greater Flushing area. Therefore, the RWCDs would not result in a significant adverse density impact on land use within the primary study area.

SECONDARY STUDY AREA

The secondary study area is farther from the project site than the primary study area, and thus land uses in the secondary study area are less likely to be affected by the RWCDs in 2018, 2028, or 2032.

The RWCDs would be consistent with the current trend of redevelopment of vacant or underutilized properties for large commercial and retail developments on Flushing Bay in the College Point subarea. While the RWCDs would not be consistent with the large industrial uses also located in this area, these uses are separated from the project site by Flushing Bay, the Whitestone Expressway, and Northern Boulevard, and thus this inconsistency would not result in any significant adverse land use impacts.

The RWCDs would be consistent with the residential, office, retail, recreational, and entertainment uses in the Corona and Flushing subareas within the secondary study area. As with the primary study area, the open space proposed as part of the RWCDs would be consistent with some passive park uses in the surrounding area, and the entertainment and retail uses would be compatible with the adjacent CitiField stadium and other cultural facilities located within the boundaries of Flushing Meadows-Corona Park. Therefore, the RWCDs would not result in a significant adverse impact on land use within the secondary study area.

ZONING

No changes to zoning would be required for any portion of the project site in Phases 1B or 2. For Phase 1A, a text amendment and special permit would be required to allow surface parking and open and enclosed, privately operated recreational uses within the District. (See **Appendix A-1** for the proposed text amendment.) This text amendment and special permit would be required only to facilitate the development of Mets replacement parking until the South Lot structured parking is completed and to allow the provision of interim recreational use for a minimum of six months of the year. The uses that would be allowed by the granting of the text amendment and special permit would be consistent with existing uses on the project site (surface parking), as well as in the primary and secondary study areas (recreational uses). With this exception, all of the development proposed for the District would be consistent with the zoning approved in 2008.

Willets Point Development

Zoning in the primary and secondary study areas would not be affected by the RWCDs in 2018, 2028, or 2032.

Therefore, there would be no adverse impacts to zoning on the project site or in the study areas as a result of the RWCDs.

PUBLIC POLICY

WILLETS POINT URBAN RENEWAL PLAN

The development that would occur within the District in Phase 1A, Phase 1B, and Phase 2 would be consistent with the maximum development envelopes, open space creation requirements, and other regulations set forth in the Willets Point URP.

DOWNTOWN FLUSHING DEVELOPMENT FRAMEWORK

The RWCDs represent a critical step in implementing the 2004 Downtown Flushing Development Framework. Development in the District and Willets West proposed as part of Phase 1A would advance a number of the Framework's fundamental goals, including the development of retail, hotel, and entertainment uses that would enhance economic growth in Downtown Flushing and the Corona neighborhood. The environmental remediation proposed as part of Phase 1A would also improve environmental conditions in the District. The parking area that would be converted to active recreational use would support other park and recreational areas surrounding the project site, including the Flushing Bay Promenade and Flushing Meadows-Corona Park.

Further development of residential, retail, community facility, public school, open space, and office uses in Phase 1B would continue to foster the integration of new development in the District with surrounding amenities, including the Flushing Bay Promenade, CitiField, Flushing Meadows-Corona Park, and Downtown Flushing and Corona. A substantial number of new housing units proposed in this phase would be affordable to a mix of incomes to help meet the growing demand for housing in Queens and the City as a whole, and would create substantial positive economic value for the City and provide a source of quality jobs for area residents.

The build-out of the remainder of the retail, hotel, residential, community facility, public school uses in the District as part of Phase 2, as well as the potential development of commercial and office space on Lot B, would facilitate the creation of a super-regional destination to complement the local and regional aspects of Downtown Flushing and Corona—a goal specifically outlined in the Framework. Therefore, the RWCDs are consistent with this policy.

PLANYC 2030 (2011)

The RWCDs would be consistent with and vital to the advancement of the goals of PlaNYC, specifically, the following:

- *Create homes for almost a million more New Yorkers while making housing more affordable and sustainable:* As discussed in Chapter 1, "Project Description," Phases 1B and 2 of the proposed project would result in the construction of up to approximately 5,850 housing units, 35 percent of which would be reserved for affordable housing. Housing units in the District would offer rental and homeownership opportunities for a range of incomes.

- *Ensure that all New Yorkers live within a 10-minute walk of a park:* No new residential uses would be created in Phase 1A of the proposed project. The minimum of six acres of publically accessible open space to be created in Phase 1B and the minimum of eight acres to be created in Phase 2 would ensure that new residents in the District would be located within a 10-minute walk of a park. The District’s residential units would also be developed in close proximity to the Flushing Meadows-Corona Park.
- *Clean up all contaminated land in New York:* As discussed in further detail in Chapter 11, “Hazardous Materials,” environmental remediation would take place across the project site as part of the RWCDS. Remediation of the Phase 1A/1B portion of the District would be complete by 2016. Remediation of the portions of the District not already developed in Phases 1A and 1B is assumed to be completed prior to 2028.
- *Expand sustainable transportation choices and ensure the reliability and high quality of our transportation network:* The Willets West entertainment and retail center to be developed in Phase 1A, and the residential and commercial uses to be developed in the District in Phases 1B and 2, would allow for more comprehensive transit-oriented development around the Mets/Willets Point stops on the No. 7 train and LIRR. The potential redevelopment of Lot B also would support more comprehensive transit-oriented development around these transportation nodes. The parking facilities proposed to be developed by 2028 and 2032 on the South Lot and Lot D would support this new regional destination center as well as the existing CitiField.
- *Open 90 percent of New York City’s rivers, harbors, and bays for recreation by reducing water pollution and preserving natural areas:* As discussed in Chapter 12, “Infrastructure,” remediation would occur on the project site as part of Phases 1A, 1B, and 2. The RWCDS would eliminate potentially polluting septic fields and any groundwater contaminants from existing auto-related uses within the District. For all three phases, the proposed project would exercise Best Management Practices to detain stormwater during rain events and pre-treat prior to discharge. Therefore, the RWCDS is expected to result in improved stormwater quality and, consequently, improved water quality in Flushing Bay.
- *Embark on a broad effort to adapt our City to the unavoidable climate shifts ahead:* As discussed in Chapter 12, in all three phases the RWCDS would require the developer to consider the most up-to-date information on the effects of climate change in the City and implement adaptation strategies where appropriate and feasible.

FLUSHING MEADOWS-CORONA PARK STRATEGIC FRAMEWORK PLAN

The RWCDS would be compatible with the goals set forth in the Flushing Meadows-Corona Park Strategic Framework Plan. The RWCDS would attract visitors to the project site that would possibly visit and use the amenities available in the park. Additionally, the open space to be developed within the District in Phases 1B and 2, and the recreational space that would be available within the District at least six months of the year during Phase 1A, would be compatible with the goals outlined in this policy.

Although the portions of the RWCDS would be developed on mapped parkland within the boundaries of Flushing Meadows-Corona Park, this development would not conflict with the Park’s Strategic Framework Plan. The areas to be affected are currently paved and used for parking to serve CitiField events, do not contribute to the passive or recreational activities occurring in the park, and have not been considered in future plans for the park, with the exception of a parking garage (rather than a parking field), which has been suggested to serve

the stadium, and the proposed creation of a transportation management association to coordinate large events and associated transportation and parking strategies.

COLLEGE POINT CORPORATE PARK

The RWCDs would not have significant adverse impacts on the College Point Corporate Park in 2018, 2028, or 2032. On the contrary, the proposed entertainment, retail, commercial, and residential uses would most likely enhance the retail uses located in the park by introducing new residential and visitor populations to the area.

Therefore, the RWCDs would not result in any significant adverse impacts to land use, zoning, or public policy that were not previously identified in the 2008 FGEIS and subsequent technical memoranda.

G. WATERFRONT REVITALIZATION PROGRAM

The WRP is the City's principal coastal zone management tool. As originally adopted in 1982 and revised in 1999, it establishes the City's policies for development and use of the waterfront. All proposed actions subject to CEQR, Uniform Land Use Review Procedure (ULURP), or other local, state, or federal agency discretionary actions that are situated within New York City's designated Coastal Zone Boundary must be reviewed and assessed for their consistency with the WRP.

The project site is located within the City's designated Coastal Zone Boundary. Therefore, in accordance with the guidelines of the *CEQR Technical Manual*, a preliminary evaluation of the RWCDs' consistency with WRP policies was undertaken (see **Appendix A-2** for the WRP Coastal Assessment Form [CAF] that was appended to the EAS and Draft Scope of Work for the proposed project). As determined by the CAF, the RWCDs requires detailed assessment for several WRP policies, as described below.

CONSISTENCY OF PROPOSED PROJECT WITH THE WATERFRONT REVITALIZATION PROGRAM POLICIES

New York City's WRP includes 10 principal policies designed to maximize the benefits derived from economic development, environmental preservation, and public use of the waterfront, while minimizing the conflicts among those objectives. For each policy and sub-policy question that was answered "yes" in the CAF, this analysis includes a discussion of the policy's applicability to the RWCDs and the RWCDs' consistency with the respective policy.

Policy 1: Support and facilitate commercial and residential development in areas well-suited to such development.

Policy 1.1: Encourage commercial and residential redevelopment in appropriate coastal zone areas.

The RWCDs would create commercial uses in 2018, 2028, and 2032, and residential uses in 2028 and 2032, including both affordable and market-rate housing. The project site is considered to be an appropriate coastal zone area for the redevelopment of such uses, as they are prevalent in the vicinity, particularly within the dense center of Downtown Flushing. The proposed community facility and open space uses would support the proposed residential and commercial uses and provide amenities for area residents and visitors. Therefore, the RWCDs would be consistent with this policy.

Policy 1.2: Encourage non-industrial development that enlivens the waterfront and attracts the public.

The proposed uses of the RWCDs in 2018, 2028, and 2032 would result in substantially greater numbers of people coming to the project area, would attract the public, and would enliven this area of land near the Flushing Bay waterfront. The proposed project also would improve connectivity between the project site and surrounding areas, including the Flushing Bay waterfront. Therefore, the RWCDs would be consistent with this policy.

Policy 1.3: Encourage redevelopment in the coastal area where public facilities and infrastructure are adequate or will be developed.

As described in the other chapters of this EIS, public facilities and infrastructure serving the project site are either presently adequate to handle the demands generated by the RWCDs in 2018, 2028, and 2032, or would be developed independently or as part of the proposed project to the level necessary to support the demands of the RWCDs. As detailed in Chapter 4, “Community Facilities,” a significant adverse impact to public day care facilities would occur in 2028 and 2032 as part of the RWCDs. For Phase 1B, the Queens Development Group (QDG) would consult with the New York City Administration for Children’s Services (ACS) to determine the appropriate way to meet demand for day care services generated by the Phase 1B development in the District. For Phase 2, EDC would require the designated developer also consult with ACS to determine the appropriate way to meet demand for day care services generated by development in the District.

The project site is well served by roadways, including Northern Boulevard, the Van Wyck Expressway, and Roosevelt Avenue, and mass transit including the No. 7 subway line, the LIRR, and the Q48 and Q66 bus routes. By 2024, a new connection between the Van Wyck Expressway and the District is anticipated to be constructed to facilitate the movement of traffic into and out of the District and minimize traffic on nearby local roadways.

As described in Chapter 11, “Infrastructure,” the District is not currently connected to the City’s sanitary sewer system. Under the RWCDs, the District would be connected to the City’s sanitary sewer system, replacing the current reliance on septic tanks. Based on current estimates, the 36-inch sanitary sewer currently under construction by EDC in the project area would have sufficient capacity to accommodate the proposed development; however, upgrades to the 37th Avenue pump station and its force main would likely be required for the later phases of the project. Verification of this requirement by DEP would be obtained prior to development of the later phases. With these measures, the infrastructure needs of future user populations within the project site would be adequately met. Therefore, the RWCDs is consistent with this policy.

Policy 4: Protect and restore the quality and function of ecological systems within the New York City coastal area.

The project site is located within the Long Island Sound Special Natural Waterfront Area (SNWA). The SNWAs are large areas with concentrations of natural resources, including wetlands, habitats, and buffer areas. The RWCDs would not involve any excavating or placing of fill within Flushing Bay or Flushing River and would not interfere with habitats or wetlands in the Long Island Sound SNWA. The RWCDs would introduce a storm water management program for the project site where one currently does not exist, which would help to protect the quality and function of the Flushing River and Flushing Bay. Furthermore, the environmental remediation of the Willets Point District would reduce

pollution flows into the Flushing River and Bay and improve the quality and functions of those systems. Therefore, the RWCDS is consistent with this policy.

Policy 4.3: Protect vulnerable plant, fish and wildlife species, and rare ecological communities. Design and develop land and water uses to maximize their integration or compatibility with the identified ecological community.

There are no terrestrial threatened or endangered species or rare ecological communities present within the project site. Because the RWCDS would not result in in-water construction activities or discharges that would have the potential to adversely affect water quality of the Flushing River or Flushing Bay, the construction and operation of Phases 1A, 1B, and 2 would not have the potential to adversely affect any plant, fish, or wildlife species. On the contrary, the environmental remediation of the project site would have positive impacts on the quality of adjacent water bodies and improve ecological communities. Therefore, the RWCDS would be consistent with this policy.

Policy 5: Protect and improve water quality in the New York City coastal area.

Policy 5.1: Manage direct or indirect discharges to waterbodies.

All phases of the RWCDS would comply with the “New York Guidelines for Urban Erosion and Sediment Control” and the *New York State Management Design Manual*. With implementation of the proposed site remediation (detailed in Chapter 10, “Hazardous Materials”) and development of the RWCDS’s stormwater management facilities, construction and operation of the RWCDS would reduce the potential for contaminants to enter Flushing Bay. The proposed remediation measures are not expected to affect the efficiency and functionality of the existing outfalls. Best management measures implemented during and after construction would include erosion and sediment control measures and treatment of stormwater as part of a stormwater pollution prevention plan (SWPPP) and would minimize potential impacts on Flushing Bay associated with stormwater runoff. The RWCDS is not expected to have a significant adverse construction impact on the water quality of Flushing Bay or the Flushing River.

All phases of the RWCDS would be consistent with the City’s goal to reduce CSO events by requiring construction and maintenance of a separate storm and sanitary sewer system. The additional sanitary flow from the RWCDS would not affect the number of annual CSO events, and water conservation measures would be employed to minimize sanitary sewage flow to the existing combined sewer system.

Stormwater generated within the project site during operation in 2018, 2028, and 2032 would be diverted and discharged through a separate stormwater collection system, to Flushing Bay via two existing outfalls on 126th and 127th Streets. As described in Chapter 12, the current stormwater conveyance system is insufficiently sized to accommodate the runoff currently being generated in the District. To eliminate these stormwater management issues, the RWCDS would require the construction of a new stormwater conveyance system, to accommodate the 3.79 acre-feet of stormwater that is beyond the discharge capacity during a 5-year storm event. With the implementation of adequate stormwater management features, stormwater flow could be controlled so as to remain within the capacity of the two existing outfalls without the need to modify the existing outfalls. In addition, QDG, and the future developer of Phase 2, would be required to prepare and implement a site stormwater management plan, to be reviewed and approved by DEP prior to commencement of construction. This plan would specify Best Management Practices and sustainable design

features to be incorporated in the project. If it is determined that the stormwater management features selected for a specific development plan do not adequately supplement the stormwater flow capacity of the existing outfalls, a new outfall will be proposed to augment the existing system.

Given that the District currently lacks sewer infrastructure, and stormwater from the existing industrial uses flows heavily into Flushing Bay, discharges from the proposed system in the future with the RWCDS in 2018, 2028, and 2032 to Flushing Bay would be an improvement over current conditions. Overall, implementation of the new system is expected to result in improved stormwater quality and, consequently, improved water quality in Flushing Bay by eliminating site flooding, improving the quality of the soil substrate of the site, and providing direct drainage to storm sewers; incorporating sustainable design features, where feasible, to reduce the discharge volume and increase the quality of stormwater discharges; and preventing stormwater generated within the District from entering the combined sewer system, which would increase the frequency and volume of combined sewer overflow (CSO) discharges.

All discharges would be required to meet applicable water quality standards of receiving waters. The projected discharges would not be expected to result in an adverse impact on Flushing Bay or the upper East River; nor would it fail to continue to meet Class I standards. As noted in Chapter 10, the life stages of estuarine-dependent and anadromous fish species, bivalves, and other macroinvertebrates found within Flushing Bay are fairly tolerant of varying environmental conditions and have developed behavioral and physiological mechanisms for dealing with these variations. Therefore, temporary, localized changes in water quality that may occur as a result of the minimal additional CSO discharge would not be expected to result in significant adverse impacts on aquatic biota. Significant adverse impacts on surface water quality would not be expected during operation of the RWCDS.

Therefore, the RWCDS is consistent with this policy.

Policy 5.2: Protect the quality of New York City's waters by managing activities that generate nonpoint source pollution.

As noted above, all phases of the RWCDS would comply with the New York Guidelines for Urban Erosion and Sediment Control and the New York State Management Design Manual. With implementation of the proposed site remediation (detailed in Chapter 10, "Hazardous Materials") and development of the proposed stormwater management facilities, construction and operation of the RWCDS would reduce the potential for contaminants to enter Flushing Bay. Additionally, the open space proposed for development in the District by 2028 and 2032 would help minimize stormwater runoff from roadways and impervious surfaces. Therefore, the RWCDS would minimize nonpoint source pollution by using Best Management Practices that include implementing stormwater management facilities where none currently exist and minimizing nonpoint source pollution.

Therefore, the RWCDS is consistent with this policy.

Policy 5.3: Protect water quality when excavating or placing fill in navigable waters and in or near marshes, estuaries, tidal marshes, and wetlands.

The RWCDS would not result in the excavating or placing of fill within Flushing Bay or Flushing River. Therefore, this policy is not applicable.

Policy 6: Minimize loss of life, structures and natural resources caused by flooding and erosion.

FEMA and New York City Building Code flood resistant design requirements would be taken into account within the design of the proposed project, while complying with the special district zoning elevation requirements. Based on the FEMA Flood Insurance Rate Maps (FIRMs), Willets West, the South Lot, and Lots B and D are within the 100-year floodplain (with flood elevation of 14 feet NGVD29). Most of the District is also within the 100-year floodplain (with flood elevation of 14 feet NGVD29), with the exception of three areas located in the northwest, along the eastern border and along Roosevelt Avenue that are within the 500-year floodplain. The existing FIRM 100-year floodplain is currently the only regulatory standard relating to elevation of new development. The City has been working with FEMA to revise the FIRMs. On February 25, 2013, FEMA released Advisory Base Flood Elevation maps for areas in New York City, including the project site. The 100-year flood ABFE for Willets West, and portions of the project site to the south of 37th Avenue, is 12 feet NAVD88. Within the District, for most of the area to the North of 37th Avenue, the 100-year ABFE is 13 feet NAVD88, with the exception of an area mostly to the north of 34th Avenue, which is outside of the advisory 100-year floodplain. Although the ABFE is subject to further review, if it is adopted as part of a future updated Flood Insurance Rate Map, the proposed project would comply with these flood elevations as required by the New York City Building Code. Raising the District portion of the project site out of the floodplain would not only minimize the potential loss of life, structures, and natural resources caused by flooding and erosion, but would also protect the City's significant investment in new infrastructure. Therefore, the RWCDS is consistent with this policy.

Policy 7: Minimize environmental degradation from solid waste and hazardous substances.

Policy 7.1: Manage solid waste material, hazardous wastes, toxic pollutants, and substances hazardous to the environment to protect public health, control pollution and prevent degradation of coastal ecosystems.

As discussed in Chapter 10, "Hazardous Materials," management of wastes generated in the cleanup and redevelopment of the project site will be conducted in accordance with applicable federal, state and local regulatory requirements and with oversight of NYC regulatory agencies. Cleanup of the soils and groundwater will reduce the potential for migration to nearby waterbodies and help improve the coastal ecosystems. Therefore, the RWCDS is consistent with this policy.

Policy 7.2: Prevent and remediate discharge of petroleum products.

The District portion of the project site has a history of automotive and other uses that are known to have resulted in extensive contamination of soil and groundwater with petroleum. As described in Chapter 10, "Hazardous Materials," prior to development in Phases 1A and 1B, remediation of soils and, if needed, groundwater would be conducted in accordance with state petroleum spill program requirements as well as NYC requirements. Remediation of the portions of the District not already developed in Phases 1A and 1B would be completed prior to 2028. Development proposed in the Willets West and Roosevelt Avenue portions of the project site are not expected to require petroleum remediation. Although the RWCDS might include petroleum storage (e.g., of fuel oil for heating new buildings), it would be in accordance with the current stringent requirements for spill prevention. As such, the RWCDS is consistent with Policy 7.2.

Policy 7.3: Transport solid waste and hazardous substances and site solid and hazardous waste facilities in a manner that minimizes potential degradation of coastal resources.

Transportation of wastes generated in the cleanup and redevelopment of the project site will be conducted in accordance with applicable regulatory requirements, including those relating to the types of trucks and the covering of trucks used for different categories of wastes and requirements relating to designated truck routes. Using the required procedures will reduce the potential for wastes to be released into or to migrate to nearby waterbodies and help improve the coastal ecosystems. New solid and hazardous waste facilities are not components of the RWCDS. Therefore, the RWCDS is consistent with this policy.

Policy 8: Provide public access to and along New York City's coastal waters.

Policy 8.1: Preserve, protect and maintain existing physical, visual and recreational access to the waterfront.

The proposed project would preserve, protect, and maintain existing physical, visual, and recreational access to the waterfront. The proposed action would not result in the provision of open space without the provision for its maintenance. The proposed project would also enhance roadways which support public access to the waterfront.

Policy 8.2: Incorporate public access into new public and private development where compatible with proposed land use and coastal location.

The proposed project would not result in any development along the shoreline; nor would it change any existing public access to the waterfront or result in significant adverse impacts to natural resources. As described below under Policy 8.3, views to coastal lands and waters from the project site are currently obstructed.

Policy 8.3: Provide visual access to coastal lands, waters and open space where physically practical.

Views to coastal lands and waters, specifically Flushing Bay and Flushing River, from the project site are currently obstructed by Van Wyck Expressway to the east, Grand Central Parkway to the west, and Northern Boulevard and Whitestone Expressway to the north. Given that there are no existing views to coastal lands or waters to preserve, no phase of the RWCDS would affect physical, visual, or recreational access to the waterfront. Therefore, the RWCDS would be consistent with this policy.

Policy 8.4: Preserve and develop waterfront open space and recreation on publicly owned land at suitable locations.

The project site is not located on the waterfront and the proposed project does not involve the acquisition of waterfront property for public access or open space. Therefore, this policy is not applicable to the proposed project.

Policy 8.5: Preserve the public interest in and use of lands and waters held in public trust by the state and city.

As a portion of the project site is mapped City parkland, it is possible that those portions of the project site could be considered as constituting lands held in public trust by the city. DPR has previously received the legislative authority to enter into leases for the use of the Willets West portion of the project site in furtherance of entertainment, trade and commerce for the benefit of the City. Specifically, Section 18-118 of the Administrative Code

(originally codified as Section 532-15.0) was enacted by the New York State Legislature under Chapter 729 of the Session Laws of 1961 and authorizes, among other things, alienation of the Citi Field parking area and permits the uses now under consideration as part of the proposed project. The statute authorizes the DPR Commissioner to enter into leases, contracts and other agreements for a multitude of purposes, including for any purpose which is of such a nature so as to foster or promote amusement, entertainment or the improvement of trade and commerce. The statute declares that such purposes, as well as others set forth in the statute, are for the benefit of the people of the City and for the improvement of, among other things, their health, welfare, recreation and prosperity, and for the improvement of trade and commerce, and are further declared to be public purposes. The proposed uses fit within the uses allowed by the above statutory provision. In addition to being allowed by the statutory provision, by introducing entertainment and commercial uses for the public, the proposed uses would improve the use of the land over its current use as a paved parking lot not open to the general public except during CitiField and occasional other events. Therefore, the proposed project is consistent with this policy.

Policy 9: Protect scenic resources that contribute to the visual quality of the New York City coastal area.

Policy 9.1: Protect and improve visual quality associated with New York City's urban context and the historic and working waterfront.

The project site is not located within a working waterfront area. The RWCDS would result in a vibrant, dynamic, mixed-use development with a minimum of 8 acres of new publicly accessible landscaped open space that would improve the visual quality of the project site. As the project site is characterized primarily by industrial shed-like buildings and surface parking lots, the RWCDS would result in a development that is more compatible with scenic elements in the area than the existing condition. Therefore, the RWCDS would be consistent with this policy.

Policy 9.2: Protect scenic values associated with natural resources.

The project site is located within the Long Island Sound Special Natural Waterfront Area (SNWA). Consistent with the goals of Policy 9.2, the proposed project would not result in any fragmentation of or structural intrusion into open space areas, and would not change the continuity or configuration of natural shorelines or associated vegetation. The proposed project would be designed with consideration of the character of adjacent open and natural areas.

Policy 10: Protect, preserve, and enhance resources significant to the historical, archaeological, and cultural legacy of the New York City coastal area.

There are no architectural resources located within the Willets West or Roosevelt Avenue portions of the project site. Therefore, there would be no adverse impacts to architectural resources from the development of these areas. The District contains the former Empire Millwork Corporation Building (State/National Register [S/NR]-eligible) which would be demolished with Phase 2 of the proposed project, resulting in a significant adverse impact to this architectural resource. The project sponsors will consult with the New York State Office of Parks, Recreation, and Historic Preservation (OPRHP) and the New York City Landmarks Preservation Commission (LPC) regarding appropriate measures to evaluate any remaining potential alternatives to demolition. If none are identified, measures to fully or partially mitigate this adverse impact have been developed, as discussed in Chapter 21,

“Mitigation.” While the demolition of the former Empire Millwork Corporation Building is a significant adverse impact on a historic resource, the building is not significant to the historical or cultural legacy of New York City’s coastal area. The achievement of this policy is not hindered by the RWCDS, and accordingly the RWCDS is consistent with Policy 10. *

A. INTRODUCTION

This chapter assesses whether any changed background conditions or the differences between the reasonable worst-case development scenario (RWCDS) and the program assessed in the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda would result in any significant adverse impacts on socioeconomic conditions that were not addressed in the 2008 FGEIS and subsequent technical memoranda. As described in the 2012 *City Environmental Quality Review (CEQR) Technical Manual*, the socioeconomic character of an area includes its population, housing, and economic activities. Socioeconomic changes may occur when a project directly or indirectly affects any of these elements.

The proposed project for the most part incorporates development that was anticipated and analyzed in the 2008 FGEIS; the current project now includes a major entertainment/retail component and parking adjacent to CitiField (Willeys West). Compared with the program analyzed in the 2008 FGEIS, the proposed project includes approximately 950,000 gross square feet (gsf) (550,000 sf of leasable area) of additional retail space, an increase resulting from the proposed 1.4 million-gsf development at Willeys West combined with a concurrent reduction in the overall amount of retail in the Special Willeys Point District from 1.7 million gsf to 1.25 million gsf. The Supplemental EIS (SEIS) also assumes the highest amount of residential use analyzed in the 2008 FGEIS (5.85 million gsf of residential development, or 5,850 residential units).

In accordance with *CEQR Technical Manual* guidelines, this analysis considers whether development of this additional space could result in significant adverse socioeconomic impacts as a result of: (1) direct displacement of residential population from the project site; (2) indirect displacement of residential population in a ¾-mile study area; (3) direct displacement of existing businesses from the project site; (4) indirect displacement of businesses in a ¾-mile study area due to increased rents; (5) indirect displacement of businesses within a larger trade area due to retail market saturation; and (6) adverse effects on specific industries.

PRINCIPAL CONCLUSIONS

Consistent with the 2008 FGEIS and subsequent technical memoranda, this analysis finds that the proposed project would not result in any significant adverse impacts to socioeconomic conditions. The following summarizes the conclusions for each of the six CEQR areas of socioeconomic concern.

DIRECT RESIDENTIAL DISPLACEMENT

The proposed project would result in the same direct residential displacement as identified in the 2008 FGEIS (one residential unit/household located in the District); there are no residential units

located on the expanded portions of the project site. Therefore, the SEIS does not require further assessment of potential socioeconomic impacts due to direct residential displacement.

INDIRECT RESIDENTIAL DISPLACEMENT

A detailed analysis finds that the proposed project would not result in significant adverse impacts due to indirect residential displacement. The proposed project would develop more total residential units (5,850 vs. 5,500) and more affordable housing (35 percent of units) than analyzed in the indirect residential displacement analysis of the 2008 FGEIS, which considered the Convention Center Scenario. The increase in the affordable housing percentage was analyzed in the subsequent Technical Memorandum No. 2 (2008), and no significant adverse impacts were identified related to that change.

The increase in the number of residential units as analyzed in the SEIS does not alter the 2008 FGEIS finding that the District is geographically separated from the at-risk population, limiting its potential to influence surrounding residential trends. Residential markets within the study area are similar to the markets described in the 2008 FGEIS; as with the FGEIS, the SEIS finds that these geographically separated communities would experience upward rent pressure with or without the proposed project due to planned projects that are within their distinct residential markets. Similar to the 2008 FGEIS, the SEIS finds that although the population that would be introduced by the proposed project may include a larger proportion of households at higher incomes as compared with the existing study area population, the proposed project's 2,048 affordable housing units would ensure that a substantial portion of the new population would have incomes that would more closely reflect existing incomes in the study area.

DIRECT BUSINESS DISPLACEMENT

The proposed project would result in the same direct business displacement identified and analyzed in the 2008 FGEIS and subsequent technical memoranda, and market conditions are similar to those described in the 2008 FGEIS; there are no businesses located in the expanded portions of the project site.¹ Therefore, the SEIS does not require further assessment of potential socioeconomic impacts due to direct business displacement.

The 2008 FGEIS found that the Willets Point Development Plan would displace approximately 260 businesses and 1,711 employees associated with those businesses. As of December 2012, there were an estimated 220 businesses and 1,353 employees still located within the District portion of the project site. As shown in **Table 3-1**, a vast majority of the remaining businesses (193 businesses, or 88 percent) are auto-related, but those businesses employ only 53 percent of the remaining employees. The remainder of the employees works in the 27 non-auto-related businesses.

While the timeline for the displacement of any individual business varies depending on its business plans and relocation efforts, overall it is anticipated that by the 2018 Build year all of the 122 remaining businesses currently located in the Phase 1A/Phase 1B portion of the project site would be displaced to accommodate development of Phase 1A. The 98 remaining business located in the Phase 2 portion of the project site would be displaced by the 2028 Build year.

¹ Any businesses locating in the District since the 2008 FGEIS have voluntarily done so knowing that they could be displaced; therefore, they do not meet the CEQR definition of direct business displacement, which is the involuntary displacement of businesses from a project site.

Table 3-1

Project Site Employment by Business Type and Sector
December 2012

North American Industry Classification System (NAICS) Economic Sector	Number of Businesses/ Institutions	Percent of Businesses/ Institutions	Number of Jobs	Jobs as a Percentage of Total
Auto-Related Businesses	193	88%	712	53%
Retail Trade (NAICS 44 & 45)	31	14%	210	16%
Repair & Maintenance Services (NAICS 811)	153	70%	457	34%
Wholesale Trade (NAICS 42) – <i>scrap yards</i>	4	2%	33	2%
Transportation & Warehousing (NAICS 48)	5	2%	12	1%
Non Auto-Related Businesses	27	12%	641	47%
Construction (NAICS 236 & 238)	6	3%	147	9%
Manufacturing (NAICS 31-33)	5	2%	72	5%
Wholesale Trade (NAICS 42)	7	3%	232	12%
Administrative and Support and Waste Management and Remediation Services (NAICS 56)	5	2%	178	11%
Arts, Entertainment & Recreation (NAICS 71)	0	0%	0	0%
Accommodation & Food Services (NAICS 72)	5	2%	12	1%
Other Services (NAICS 813)	0	0%	0	0%
Total District Businesses	220	100%	1,353	100%
Notes: Employment figures for auto repair and maintenance establishments were derived from AKRF site visits, interviews by Howard/Stein-Hudson, Cornerstone and EDC business interviews, and estimates for businesses based on New York State Department of Labor (DOL) sector averages for Queens County and Dun and Bradstreet.				
Sources: AKRF, Inc., Howard/Stein-Hudson Business Survey, Cornerstone interviews, EDC, DOL				

EDC has contracted with Cornerstone Group, a business relocation expert, to provide relocation assistance and advisory services to impacted businesses in Willets Point. Cornerstone Group has been engaged in outreach to tenant businesses since January 2008 and commenced its most recent round of outreach to affected Willets Point businesses on City-owned property in September 2012. They have already identified several potential relocation sites and will continue to work with business to provide relocation assistance.

EDC retained LaGuardia Community College (LAGCC) to develop a Workforce Assistance Plan for District workers who are directly displaced by the project. The program provides displaced workers with services such as job training and job placement services, ESL and GED coursework, and additional social services. To date, there have been over 600 program participants and the program is ongoing.

INDIRECT BUSINESS DISPLACEMENT DUE TO INCREASED RENTS

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. The SEIS preliminary assessment finds that these additional commercial and entertainment uses would not introduce trends that are substantially different from those identified in the 2008 FGEIS, and would not result in significant indirect business displacement due to increased rents.

While the proposed project's uses would be a substantial addition to the ¼-mile study area, they would not be new types of uses within the study area, and therefore would not introduce a new trend that could substantially alter economic patterns. The study area is already experiencing a trend toward increased retail and residential development. The proposed project's additional retail would serve existing residents, and would accommodate future consumer demand

introduced by residents of planned developments and the proposed project. The uses, residents, and workers introduced by the proposed project represent a continuation of existing trends, rather than a new trend that would place upward pressure on office rents in the study area. Similarly, there are already destinations in the study area that offer entertainment and/or recreational opportunities, including Flushing Bay Promenade, CitiField, USTA National Tennis Center, Flushing Meadows-Corona Park, College Point Multiplex Theater, and Downtown Flushing.

INDIRECT BUSINESS DISPLACEMENT DUE TO RETAIL MARKET SATURATION

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. Similar to the 2008 FGEIS, the SEIS analysis finds that the proposed project, including these additional proposed retail uses, would not substantially raise retail market capture rates within a 5-mile Primary Trade Area and, therefore, would not have the potential to adversely affect competitive stores in the Primary Trade Area.

The SEIS preliminary assessment finds that the retail introduced by the proposed project would result in trade area capture rates well below 100 percent by 2032, which is the *CEQR Technical Manual* threshold requiring detailed analysis.¹ However, to maintain a scope of analysis consistent with that performed for the 2008 FGEIS, the SEIS includes a detailed analysis of indirect business displacement due to retail market saturation.

Similar to the analysis in the 2008 FGEIS, the detailed analysis focuses on grocery stores in the immediate vicinity of the proposed project, in particular, because grocery stores generally serve as anchors for retail concentrations, and the proposed project could introduce stores offering products that substantially overlap with typical grocery store offerings. In addition, the SEIS detailed analysis examines the future viability of anchors in regional retail centers, including movie theaters and restaurants, because the Willets West component of the proposed project would constitute a major new shopping and entertainment center, adding destination retail space to the Primary Trade Area.

The detailed analysis finds that the amount of indirect business displacement due to competition from the proposed project would be minimal, is not expected to jeopardize the viability of any neighborhood retail strips, and is not expected to diminish the level of services provided. Therefore, the proposed project would not result in significant adverse impacts due to retail market saturation.

ADVERSE EFFECTS ON A SPECIFIC INDUSTRY

The proposed project would result in the same direct business displacement as analyzed in the 2008 FGEIS, and would not present any new or different uses that would alter the findings of the 2008 FGEIS with respect to potential effects on the auto industry or industries dependent on auto repair. Therefore, no further assessment of this issue of concern is required for the SEIS.

¹ The 2008 FGEIS analysis of indirect business displacement due to competition was performed under the 2001 *CEQR Technical Manual*, which required detailed analysis even when capture rates were below 100 percent. The 2012 *CEQR Technical Manual* does not require similar detailed analysis if capture rates with the proposed project do not exceed 100 percent.

B. SUMMARY OF FINDINGS, 2008 FGEIS, AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS concluded that by 2017, the Willets Point Development Plan would not result in any significant adverse impacts as measured by the following socioeconomic areas of concern prescribed in the 2001 *CEQR Technical Manual*: 1) direct displacement of a residential population; 2) direct displacement of existing businesses and institutions; 3) indirect (secondary) displacement of a residential population; 4) indirect displacement of businesses and institutions due to increased rents; 5) indirect displacement of businesses due to competition; and 6) adverse effects on specific industries. Subsequent technical memoranda revisited the socioeconomic analyses and findings from the 2008 FGEIS, and determined that the project modifications, changes to background conditions, and changes in methodology would not result in any significant adverse impacts that were not identified in the FGEIS. The following summarizes the 2008 FGEIS and subsequent technical memoranda findings for each area of CEQR socioeconomic concern.

DIRECT RESIDENTIAL DISPLACEMENT

The 2008 FGEIS found that the proposed Plan would directly displace one residential unit (one household) in the District, and that the displacement of one household would not have the potential to result in significant adverse impacts due to direct residential displacement.

DIRECT BUSINESS AND INSTITUTIONAL DISPLACEMENT

The 2008 FGEIS found that the proposed Plan and anticipated future development on Lots B and D would not result in significant adverse impacts due to direct business and institutional displacement. The proposed Plan was projected to directly displace approximately 260 businesses and institutions (approximately 1,711 employees) that provide a variety of products and services within numerous economic sectors, including manufacturing, wholesale trade, retail trade, transportation and warehousing, accommodation and food services, and repair and maintenance services. Although the proposed Plan was found to displace businesses and institutions that employ many workers, and offer products and services valued by certain consumers, these businesses and institutions were determined not to be of substantial economic value to the region or City as defined under CEQR. The District's businesses are not unique; similar services and products are provided throughout Queens, the City, and the region. In addition, the vast majority of these businesses and institutions would be able to relocate to other properties within Queens or the City. Although rental costs would likely increase—as a result of the lower rents currently paid in the District compared with other manufacturing areas, and a competitive industrial real estate market citywide—most of these businesses would remain viable elsewhere.

INDIRECT RESIDENTIAL DISPLACEMENT DUE TO INCREASED RENTS

The 2008 FGEIS and subsequent technical memoranda found that the proposed Plan and anticipated future development on Lots B and D would not result in significant adverse impacts due to indirect residential displacement. A detailed analysis of indirect residential displacement determined that the study area contained an estimated 2,134 households (approximately 5,726 residents) in eight Census tracts (381, 853, 865, 867, 871, 875, 889.02, and 907) that were considered to be “at risk” of indirect residential displacement if their rents were to increase.

However, the 2008 FGEIS analysis concluded that significant indirect residential displacement of this at risk population would not occur as a result of the Plan for the following reasons:

- The District is geographically separated from the identified at-risk population, limiting its potential to influence residential trends in those areas.
- Planned residential developments located between the District and the identified at-risk population (i.e., Flushing Commons and Sky View Parc) are likely to have a greater influence on residential market trends in those tracts than the proposed Plan and anticipated future development on Lots B and D.
- By adding new housing units, the proposed Plan could serve to relieve rather than increase market pressure in the study area.
- The proposed Plan would introduce 1,100 affordable housing units to the study area. Although the population that would be introduced by the proposed Plan may include a larger proportion of households at higher incomes as compared with the existing study area population, the proposed Plan's affordable housing component would ensure that a substantial portion of the new population would have incomes that would more closely reflect existing incomes in the study area.

Subsequent technical memoranda found that the increase in the percentage of affordable housing units would not alter the finding that the proposed Plan would not result in significant adverse impacts due to indirect residential displacement.

INDIRECT BUSINESS AND INSTITUTIONAL DISPLACEMENT DUE TO INCREASED RENTS

The 2008 FGEIS found that the proposed Plan and anticipated future development on Lots B and D would not result in significant indirect business and institutional displacement impacts due to increased rents under either scenario (with or without the convention center). While the introduction of new residents, workers, and visitors to the District would alter existing economic patterns within the District, these changes would not lead to substantial indirect business displacement within the broader study area. Existing local retail establishments in the study area would continue to be more convenient to study area residents outside of the District, while the proposed Plan's residents and visitors—especially convention center and hotel visitors—would shop and dine primarily at retail establishments in the District. The proposed Plan would therefore not result in substantial changes in demand for goods and services that would alter economic conditions in the broader study area. The proposed Plan and anticipated future development on Lots B and D would represent a continuation of existing trends toward the development of retail, office, hotel, and residential uses in the study area, rather than the introduction of a new trend that would change existing economic patterns in the study area.

INDIRECT BUSINESS DISPLACEMENT DUE TO COMPETITION

The 2008 FGEIS analysis found that the proposed Plan would not substantially raise retail capture rates within the Primary Trade Area and, therefore, would not have the potential to adversely affect competitive stores in the Primary Trade Area. The analysis concluded that the proposed Plan would not raise retail capture rates within the Primary Trade Area to the extent that retail supply would out proportion demand, the proposed Plan would not have the potential to significantly affect competitive stores in the Primary Trade Area.

Within the 1½-Mile Trade Area, the detailed analysis focused on grocery stores, because grocery stores often serve as anchors for local retail concentrations. The analysis concluded that local residents would continue to shop at existing grocery stores for their convenience, specialized goods and services familiar to an ethnic community, and public transit accessibility. Although a potential supermarket or wholesale club in the District was found to be potentially competitive with nearby supermarkets and grocery stores within the 1½-Mile Trade Area, such uses were not expected to have a substantial negative effect on nearby grocery stores, nor would they jeopardize the viability of any retail strips in the study area.

Overall, the amount of indirect business displacement due to competition from the proposed Plan and anticipated future development on Lots B and D was predicted to be minimal, and was not expected to jeopardize the viability of any neighborhood retail strips or diminish the level of services provided.

ADVERSE EFFECTS ON SPECIFIC INDUSTRIES

The 2008 FGEIS found that the proposed Plan and anticipated future development on Lots B and D would not result in significant adverse impacts on any specific industry. Although a large concentration of auto-related uses (227 businesses) was predicted to be displaced from the District, these displaced businesses and their associated employment were found not to significantly impact the industry as a whole. The potentially displaced businesses and employment represented less than 5 percent of citywide employment within the auto-related sectors (including wholesale trade, retail trade, transportation and warehousing, and other services), and the businesses could relocate within the City, potentially in other auto-related clusters, thereby maintaining existing business and employment counts within the industry. Additionally, with 3,642 auto-related businesses within New York City, auto-related goods and services were found to be available elsewhere. Therefore, it was concluded that the potential displacement of these uses would not jeopardize the viability of any industries that rely on those services.

C. METHODOLOGY

This chapter has been prepared in accordance with the guidelines of the 2012 *CEQR Technical Manual*.

BACKGROUND

Under CEQR, the socioeconomic character of an area includes its population, housing, and economic activity. Although socioeconomic changes may not result in impacts under CEQR, they are disclosed if they would affect land-use patterns, low-income populations, the availability of goods and services, or economic investment in a way that changes the socioeconomic character of the area. In some cases, these changes may be substantial but not adverse. In other cases, these changes may be good for some groups but bad for others. The objective of the CEQR analysis is to disclose whether any changes created by the project would have a significant impact compared with what would happen in the No Action condition.

An assessment of socioeconomic impacts distinguishes between impacts on the residents and businesses in an area and separates these impacts into direct and indirect displacement for both of those segments. Direct displacement occurs when residents or businesses are involuntarily displaced from the actual site of the proposed project or sites directly affected by it. For

example, direct displacement would occur if a currently occupied site were redeveloped for new uses or structures or if a proposed easement or right-of-way encroached on a portion of a parcel and rendered it unfit for its current use. In these cases, the occupants of a particular structure to be displaced can usually be identified, and therefore the disclosure of direct displacement focuses on specific businesses and a known number of residents and workers.

Indirect or secondary displacement occurs when residents, businesses, or employees are involuntarily displaced due to a change in socioeconomic conditions in the area caused by the proposed project. Examples include the displacement of lower-income residents who are forced to move due to rising rents caused by higher-income housing introduced by a proposed project. Examples of indirect business displacement include higher-paying commercial tenants replacing industrial uses when new uses introduced by a proposed project cause commercial rents to increase. Unlike direct displacement, the exact occupants to be indirectly displaced are not known. Therefore, an assessment of indirect displacement usually identifies the size and type of groups of residents, businesses, or employees potentially affected.

Some projects may affect the operation and viability of a specific industry not necessarily tied to a specific location. An example would be new regulations that prohibit or restrict the use of certain processes that are critical to certain industries. In these cases, the CEQR review process may involve an assessment of the economic impacts of the project on that specific industry.

DETERMINING WHETHER A SOCIOECONOMIC ASSESSMENT IS APPROPRIATE

According to the *CEQR Technical Manual*, a socioeconomic assessment should be conducted if a project may be reasonably expected to create socioeconomic changes in the area affected by the project that would not be expected to occur in the absence of the project. The following screening assessment considers threshold circumstances identified in the *CEQR Technical Manual* (enumerated below) that can lead to socioeconomic changes warranting further assessment in the SEIS.

- 1. Direct Residential Displacement: Would the project directly displace residential population to the extent that the socioeconomic character of the neighborhood would be substantially altered? Displacement of fewer than 500 residents would not typically be expected to alter the socioeconomic character of a neighborhood.***

The proposed project would result in the same direct residential displacement as identified in the 2008 FGEIS (one residential unit/household located in the District); there are no residential units located on the expanded portions of the project site. Therefore, the SEIS does not require further assessment of potential impacts due to direct residential displacement.

- 2. Direct Business Displacement: Would the project directly displace more than 100 employees? If so, assessments of direct business displacement and indirect business displacement are appropriate.***

The proposed project would result in direct displacement from the same sites that were analyzed in the 2008 FGEIS, and would displace the same types of businesses as analyzed in the 2008 FGEIS. Therefore, the proposed project would not result in impacts due to direct business displacement that are new or different than those identified in the 2008 FGEIS, and further assessment of this issue as part of the SEIS is unwarranted.

The SEIS presents an estimate of the numbers of businesses and employs that remain on the project site, and discloses the anticipated timing of their displacement.

3. ***Direct Business Displacement: Would the project directly displace a business whose products or services are uniquely dependent on its location, are the subject of policies or plans aimed at its preservation, or serve a population uniquely dependent on its services in its present location? If so, an assessment of direct business displacement is warranted.***

The proposed project would result in direct displacement from the same sites that were analyzed in the 2008 FGEIS, and the nature and types of displaced businesses are the same as analyzed in the 2008 FGEIS. Therefore, further assessment of this issue as part of the SEIS is unwarranted.

4. ***Indirect Displacement due to Increased Rents: Would the project result in substantial new development that is markedly different from existing uses, development, and activities within the neighborhood? Residential development of 200 units or less or commercial development of 200,000 square feet or less would typically not result in significant socioeconomic impacts. For projects exceeding these thresholds, assessments of indirect residential displacement and indirect business displacement are appropriate.***

The proposed project would develop more total residential units (5,850 vs. 5,500) and more affordable housing (35 percent of units) than analyzed in the indirect residential displacement analysis of the 2008 FGEIS, which considered the Convention Center Scenario. Since the proposed project would result in 350 more residential units than analyzed in the 2008 FGEIS and subsequent technical memoranda, an assessment of potential indirect residential displacement is warranted.

While the 2008 FGEIS found that the economic patterns generated by the Willets Point Development Plan would not lead to substantial changes in demand for goods and services that would alter economic conditions in the study area, the proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. Therefore, an assessment of indirect business displacement due to increased rents is warranted.

5. ***Indirect Business Displacement due to Retail Market Saturation: Would the project result in a total of 200,000 sf or more of retail on a single development site or 200,000 sf or more of region-serving retail across multiple sites? This type of development may have the potential to draw a substantial amount of sales from existing businesses within the study area, resulting in indirect business displacement due to market saturation.***

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS. Therefore, a preliminary assessment is warranted to estimate whether the retail introduced by the proposed project would result in capture rates in excess of 100 percent, which is the *CEQR Technical Manual* threshold requiring detailed analysis.

6. ***Adverse Effects on Specific Industries: Is the project expected to affect conditions within a specific industry? This could affect socioeconomic conditions if a substantial number of workers or residents depend on the goods or services provided by the affected businesses,***

or if the project would result in the loss or substantial diminishment of a particularly important product or service within the city.

The proposed project would result in direct displacement from the same sites that were analyzed in the 2008 FGEIS, and would displace the same types of businesses as analyzed in the 2008 FGEIS. Therefore, the proposed project would not result in adverse effects on specific industries, and no further assessment of this issue of concern is required for the SEIS.

ANALYSIS FORMAT

Based on *CEQR Technical Manual* guidelines, the analyses of indirect residential and business displacement begin with a preliminary assessment. The objective of the preliminary assessment is to learn enough about the potential effects of the proposed project to either rule out the possibility of significant adverse impacts or determine that a more detailed analysis is required to fully determine the extent of the impacts. A detailed analysis is designed to examine existing conditions and then project conditions forward into the future without the proposed project, incorporating the most recent information available on known land-use proposals and changes in anticipated growth. The future condition with the proposed project in 2032 is then described, and the differences between the future without and with the proposed project are measured. The analysis focuses on the year 2032 full build condition because this condition has the greatest potential for socioeconomic impacts; if significant adverse impacts are identified by 2032, the analysis will then consider the 2018 and 2028 interim build conditions to determine the earliest point at which significant adverse impacts would occur so that mitigation could be implemented within an appropriate timeframe. To the extent that specific program elements could potentially alter the conclusions in the 2008 FGEIS and subsequent technical memoranda, the SEIS focuses on evaluating the potential significant adverse impacts of those elements.

For indirect residential displacement, a detailed analysis was required in order to rule out the potential for significant adverse impacts. Preliminary assessments were sufficient to conclude that the proposed project would not result in any significant adverse socioeconomic impacts due to indirect business displacement from increased rents or due to retail market saturation. However, to maintain a scope of analysis consistent with that performed for the 2008 FGEIS, this SEIS includes a detailed analysis of indirect business displacement due to retail market saturation.

STUDY AREA DEFINITION

According to the *CEQR Technical Manual*, the socioeconomic study area typically reflects the land use study area, and should reflect the scale of the project relative to the area's population. As described in Chapter 3, "Land Use, Zoning, and Public Policy," the analysis of land use, zoning, and public policy uses a ¼-mile primary study area and a ¾-mile secondary study area. The *CEQR Technical Manual* also explains that as the socioeconomic assessment seeks to assess change relative to the study area population, projects that would result in a relatively large increase in population may be expected to have potential indirect effects on a larger study area. Therefore, the study area for the socioeconomic assessment of indirect residential and business displacement reflects a ¾-mile perimeter. In order to analyze socioeconomic data, the boundaries of the study area were modified to include all census tracts that fall within the study area. The resulting study area for this analysis is defined as Queens Census Tracts 373, 379, 381,

383.01, 399, 401, 403, 405, 415, 427, 797.01, 797.02, 849, 853, 865, 869, 871, 889.01, and 907 (see **Figure 3-1**).¹

As shown in **Figure 3-1**, the residential study area has been divided into the following subareas, which approximate the District and the neighborhoods that surround it:

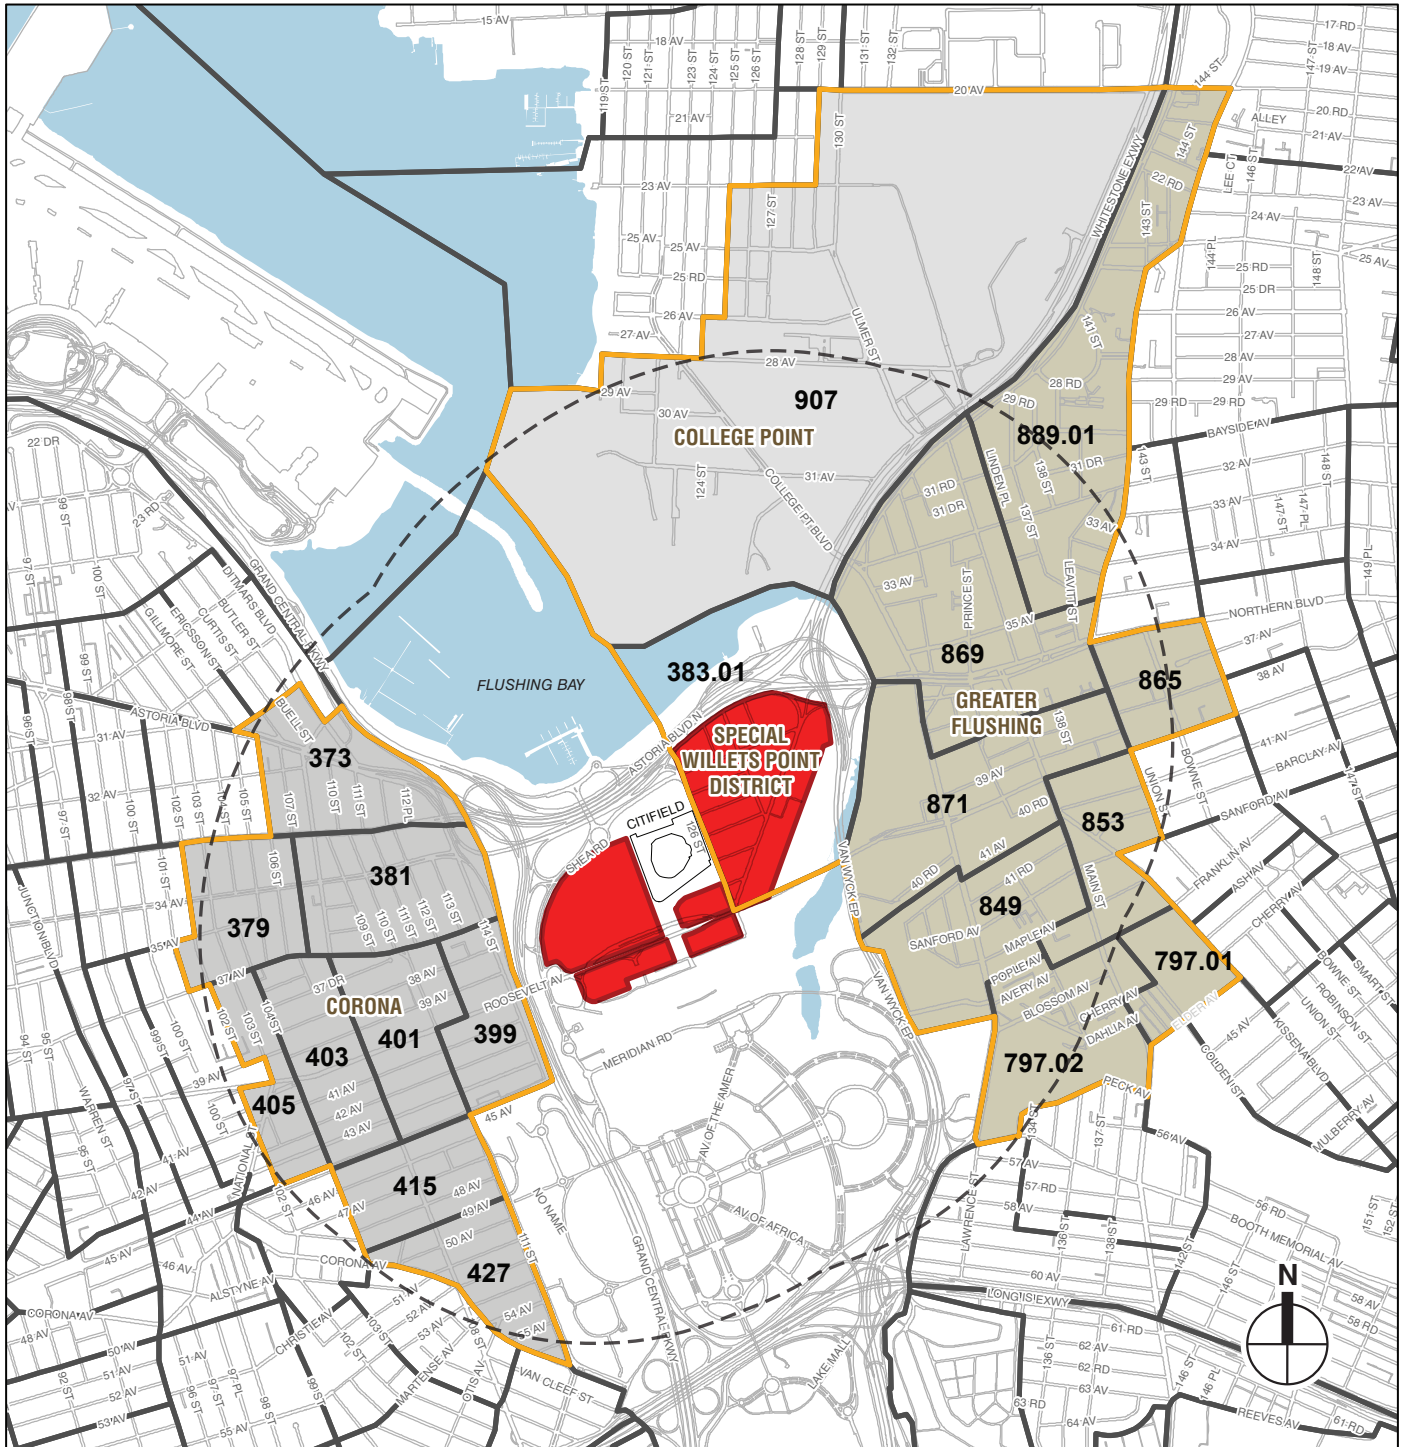

- **Special Willets Point District: Census Tract 383.01.** This area encompasses all of the Special Willet Point District.
- **Greater Flushing: Census Tracts 797.01, 797.02, 849, 853, 865, 869, 871, and 889.01.** This area extends east of the Flushing River from Kissena Corridor Park in the south to the Whitestone Expressway in the north; and to Parsons Boulevard, 149th Street, and Kissena Boulevard in the east.
- **Corona: Census Tracts 373, 379, 381, 399, 401, 403, 405, 415, and 427.** This area is roughly bounded by the Grand Central Parkway to the north, Corona Avenue to the south, 102nd Street to the west, and Grand Central Parkway and 111th Street to the east.
- **College Point: Census Tract 907.** This area extends west of the Whitestone Expressway between 20th Avenue in the north and the Flushing River in the south, and is roughly bounded by 129th Street, 125th Street, 124th Street, and Flushing Bay to the west.

The study area for the analysis of indirect business displacement due to retail market saturation was defined as a “primary trade area,” which is the area from which the bulk of new stores’ sales are likely to be derived. Given the scale and type of retail offerings possible under the proposed project, the Primary Trade Area was defined as the area within an approximately 5-mile radius around the District, bounded by Long Island Sound on the north, the East River on the west, Alley Pond Park on the east, and Rockaway Boulevard on the south (see **Figure 3-2**).

DATA SOURCES

Data related to residential demographic conditions, including population, housing, and income data, were obtained from the U.S. Census Bureau’s 2010 Census and the 2007-2011 American Community Survey (ACS). Land use and parcel data were collected from the New York City Department of Finance’s Real Property Assessment Data (RPAD) 2012 database. Estimates of rent-regulated housing were obtained from the New York State Department of Housing and Community Renewal (DHCR), compiled by the New York City Department of City Planning (DCP) Housing, Economic, and Infrastructure Planning (HEIP) Division from March 2008. Data relating to low income renters was obtained from Public Use Microdata Sample (PUMS) data for 2007-2011 ACS estimates of household income by tenure and household size. The PUMS data was provided by DCP for Public Use Microdata Area (PUMA) 4107, which approximates Queens Community District 4. Additional real estate data were obtained from Prudential Douglas Elliman Real Estate, Streeteasy.com, and other online resources. Employment, retail

¹ Although most of the area of Census Tract 797.01 falls outside of the ¾-mile perimeter, it was included for purposes of comparison with 2000 Census data. In addition, some census tract boundaries for 2000 were altered for the 2010 Census. For 2000 Census data, the ¾-mile study area included the following census tracts: 373, 379, 381, 399, 401, 403, 405, 415, 427, 797, 851, 853, 865, 867, 871, 875, 889.01, 889.02, 907, and Block Group 1 of Census Tract 383. The 2010 boundaries for Census Tracts 373, 381, and 399 include a small area to the east of the 2000 Census boundaries for those tracts, bounded by Northern Boulevard, 44th Avenue, Grand Central Parkway, and 14th Street. This area includes only landscaped areas, and does not contain any residential units or businesses.

- Census Tract

sales, and retail expenditure potential data were obtained from ESRI, Inc., a commercial data provider. The inventory of businesses currently located on the project site based on data provided by the Cornerstone Group, and supplemented by AKRF field surveys. The overall analysis is also supported by field visits to the study area conducted in November and December 2012.

D. UPDATE ON DIRECT BUSINESS DISPLACEMENT

The 2008 FGEIS found that the Willets Point Development Plan's displacement of approximately 260 businesses and 1,711 employees associated with the displaced business (shown in **Table 3-2**) would not result in significant adverse socioeconomic impacts.

Table 3-2
Project Site Employment by Business Type and Sector
As Reported in 2008 FGEIS

North American Industry Classification System (NAICS) Economic Sector	Number of Businesses/ Institutions	Percent of Businesses/ Institutions	Number of Jobs	Jobs as a Percentage of Total
Auto-Related Businesses	227	87%	1,057	62%
Retail Trade (NAICS 44 & 45)	54	21%	423	25%
Repair & Maintenance Services (NAICS 811)	163	63%	561	33%
Wholesale Trade (NAICS 42) – <i>scrap yards</i>	5	2%	58	3%
Transportation & Warehousing (NAICS 48)	5	2%	15	1%
Non Auto-Related Businesses	33	13%	642	38%
Construction (NAICS 236 & 238)	8	3.1%	153	9%
Manufacturing (NAICS 31-33)	5	2%	79	5%
Wholesale Trade (NAICS 42)	5	2%	210	12%
Administrative and Support and Waste Management and Remediation Services (NAICS 56)	6	2.3%	180	11%
Arts, Entertainment & Recreation (NAICS 71)	1	0.4%	11	0.6%
Accommodation & Food Services (NAICS 72)	7	3%	21	1%
Other Services (NAICS 813)	1	0.4%	0	0%
Total District Businesses	260	100%	1,711	100%
Notes: Employment figures for auto repair and maintenance establishments were derived from AKRF site visits, interviews by Howard/Stein-Hudson and NYCEDC business interviews, and estimates for businesses based on DOL sector averages for Queens County. Sources: AKRF, Inc., Howard/Stein-Hudson Business Survey, EDC, DOL				

The proposed project would result in direct business displacement from the same sites that were analyzed in the 2008 FGEIS and subsequent technical memoranda, and market conditions are similar to those described in the 2008 FGEIS. Therefore, no further analysis is warranted. This section provides an updated profile of the businesses remaining within the District portion of the project site.

As of December 2012, there were an estimated 220 businesses and 1,353 employees still located within the District portion of the project site. As shown in **Table 3-3**, a vast majority of the remaining businesses (193 businesses, or 88 percent) are auto-related, but those businesses employ only 53 percent of the remaining employees. The remainder of the employees work in the 27 non-auto-related businesses. In addition, despite a reduction in the overall numbers of businesses within the District portion of the project site, the distribution of businesses between auto-related and non-auto-related is virtually the same as in 2008: as of December 2012, 88 percent of remaining businesses within the District portion of the project site are auto-related, as compared with 87 percent in 2008.

Table 3-3

Project Site Employment by Business Type and Sector
December 2012

North American Industry Classification System (NAICS) Economic Sector	Number of Businesses/ Institutions	Percent of Businesses/ Institutions	Number of Jobs	Jobs as a Percentage of Total
Auto-Related Businesses	193	88%	712	53%
Retail Trade (NAICS 44 & 45)	31	14%	210	16%
Repair & Maintenance Services (NAICS 811)	153	70%	457	34%
Wholesale Trade (NAICS 42) – <i>scrap yards</i>	4	2%	33	2%
Transportation & Warehousing (NAICS 48)	5	2%	12	1%
Non Auto-Related Businesses	27	12%	641	47%
Construction (NAICS 236 & 238)	6	3%	147	9%
Manufacturing (NAICS 31-33)	5	2%	72	5%
Wholesale Trade (NAICS 42)	7	3%	232	12%
Administrative and Support and Waste Management and Remediation Services (NAICS 56)	5	2%	178	11%
Arts, Entertainment & Recreation (NAICS 71)	0	0%	0	0%
Accommodation & Food Services (NAICS 72)	5	2%	12	1%
Other Services (NAICS 813)	0	0%	0	0%
Total District Businesses	220	100%	1,353	100%
Notes: Employment figures for auto repair and maintenance establishments were derived from AKRF site visits, interviews by Howard/Stein-Hudson, Cornerstone and EDC business interviews, and estimates for businesses based on DOL sector averages for Queens County and Dun and Bradstreet. Sources: AKRF, Inc., Howard/Stein-Hudson Business Survey, Cornerstone interviews, EDC, DOL				

While the timeline for the displacement of any individual business varies depending on its business plans and relocation efforts, overall it is anticipated that by 2018 all of the 122 remaining businesses currently located in the Phase 1A/Phase 1B portion of the project site would be displaced to accommodate development of Phase 1A. The 98 remaining business located in the Phase 2 portion of the project site would be displaced by 2028.

EDC has contracted with Cornerstone Group, a business relocation expert, to provide relocation assistance and advisory services to impacted businesses in Willets Point. Cornerstone Group has been engaged in outreach to tenant businesses since January 2008 and commenced its most recent round of outreach to affected Willets Point businesses on City-owned property in September 2012. They have already identified several potential relocation sites and will continue to work with business to provide relocation assistance.

EDC retained LAGCC to develop a Workforce Assistance Plan for District workers who are directly displaced by the project. The program provides displaced workers with services such as job training and job placement services, ESL and GED coursework, and additional social services. To date, there have been over 600 program participants and the program is ongoing.

E. PRELIMINARY ASSESSMENT

Under *CEQR Technical Manual* guidelines, the first step in a socioeconomic impact analysis is a preliminary assessment. This section examines three areas of potential socioeconomic impact in relation to the proposed project: 1) indirect residential displacement; 2) indirect business displacement due to increased rents; and 3) indirect business displacement due to retail market saturation. The goal of a preliminary assessment is to learn enough about the potential effects of a proposed project either to rule out the possibility of significant impacts, or to establish that a

more detailed analysis will be required to determine whether the proposed project would lead to significant adverse impacts.

For one of the three issue areas—indirect residential displacement—the preliminary assessment indicates that a more detailed analysis is necessary to adequately assess whether the proposed project would have significant adverse impacts. For the remaining two issue areas—indirect business displacement due to increased rents and due to retail market saturation—the preliminary assessment was sufficient to conclude that the proposed project would not result in significant adverse impacts. However, a detailed analysis of indirect business displacement due to retail market saturation is provided in order to maintain a consistent scope of analysis between the 2008 FGEIS and this SEIS.

INDIRECT RESIDENTIAL DISPLACEMENT

Indirect residential displacement usually results from substantial new development that is markedly different from existing uses and activity in an area, which causes increased property values in the area. Increased property values lead to increased rents, which can make it difficult for some existing residents to remain in their homes.

The indirect residential displacement assessment aims to determine whether the proposed project would either introduce a trend or accelerate an existing trend of changing socioeconomic conditions that may have the potential to displace a residential population and substantially change the socioeconomic character of the neighborhood. This preliminary assessment follows the step-by-step preliminary assessment guidelines of the *CEQR Technical Manual*.

Step 1: Determine if the proposed project would add new population with higher average incomes compared with the average incomes of the existing populations and any new population expected to reside in the study area without the project.

The $\frac{3}{4}$ -mile socioeconomic study area includes the Queens neighborhoods of College Point, Corona, and Greater Flushing. College Point is predominantly industrial with concentrations of residential uses, predominantly one to four unit buildings, north of 26th Avenue. Corona is a predominantly residential area, with concentrations of older, one to four unit buildings throughout the area, and commercial uses along the major streets. Flushing is a thriving business and residential area, with large Chinese and Korean communities, concentrations of mixed-use buildings, and one public housing development. According to 2007-2011 ACS data, the average household income for the study area was \$61,715 (See **Table 3-4**). This was lower than the average household income in Queens (\$75,513) and in New York City as a whole (\$84,079) during the same time. Average household income decreased in the study area by 2.7 percent between 1999 and 2007-2011. Over that same time period, average household income decreased in Queens by 1.8 percent and increased in New York City as a whole, by 1.1 percent.

The proposed project would add 2,490 residential units by 2028, of which 872 would be affordable units. By 2032, the proposed project would add another 3,360 residential units to the study area, of which 1,176 would be affordable units, for a total of 5,850 residential units, including 2,048 affordable units. At this time the levels of affordability have not been defined, but it is expected that the affordable housing would be made available to a mix of low- and moderate-income residents. A total of 3,802 residential units would be market rate and would be expected to be priced on the high end of the market for the study area.

Table 3-4
Average Household Income (1999, 2007-2011)

Area	1999	2007-2011	Percent Change
Study Area	\$63,452	\$61,715	-2.7%
Queens	\$76,905	\$75,513	-1.8%
New York City	\$83,124	\$84,079	1.1%
Notes: 1. Average household income for the study area was estimated based on a weighted average of mean household income for the census tracts in the study area. 2. The ACS collects data throughout the period on an on-going, monthly basis and asks for respondents' income over the "past 12 months." The 2007-2011 ACS data therefore reflects incomes over 2007 and 2011, while Census 2000 data reflects income over the prior calendar year (1999). The mean household income for both time periods is presented in 2012 dollars using the U.S. Department of Labor's 2012 half-year average Consumer Price Index for the "New York-Northern New Jersey-Long Island Area."			
Sources: U.S. Census Bureau, 2000 Census, Summary File 3; 2007-2011 American Community Survey; U.S. Department of Labor Bureau of Labor Statistics; AKRF, Inc.			

Based on the HUD Median Family Income for New York City (\$65,000), and assuming that households spend 30 percent of their household income on housing, the average household income of the residents of the affordable housing component of the proposed project would be comparable to the current average household income for the study area. Therefore, it is expected that the average household income of the total population introduced by the proposed project—including both the affordable and market rate housing—would exceed the average incomes of the existing population, and would be comparable to any new population expected to reside in the study area without the project. Based on this finding, the assessment proceeds to Step 2.

Step 2: Determine if the project's increase in population is large enough relative to the size of the population expected to reside in the study area without the project to affect real estate market conditions in the study area.

According to data from the 2010 Census, the ¾-mile study area had a population of 91,156 residents in 2010 (See **Table 3-5**). This represents an approximately 10.4 percent increase in residents since 2000, which is substantially greater than the population increases in Queens County (0.1 percent) and New York City (2.1 percent) over the same period.

Table 3-5
2000 and 2010 Population

Area	2000	2010	Percent Change
Study Area	82,574	91,156	10.4%
Queens County	2,229,379	2,230,722	0.1%
New York City	8,008,278	8,175,133	2.1%
Sources: U.S. Census Bureau, 2000 Census, Summary File 1; 2010 Census, Summary File 1; AKRF, Inc.			

The proposed project would introduce an estimated 16,497 residents to the study area. As shown in **Table 3-6**, when compared with the population expected to reside in the study area by 2032 in the future without the proposed project (the No-Action Condition), the proposed project would increase the 2032 study area population by approximately 16.4 percent.

Table 3-6
Estimated Population in the 3/4-Mile Study Area:
2032 No-Action and With-Action Conditions

	Population			Percent Change (No-Action and With-Action Condition)
	2010	No-Action Condition 2032	With-Action Condition 2032	
Study Area	91,156	100,823	117,320	16.4%
Notes: Population estimates for planned projects in the No Action and With Action conditions assume an average household size of 2.82 persons, the average household size for Queens.				
Sources: Census 2010, New York City Department of City Planning, AKRF, Inc.				

According to *CEQR Technical Manual* methodology, a population increase greater than 10 percent warrants a detailed analysis to determine a project's potential for significant adverse impacts due to indirect residential displacement. Therefore, a detailed analysis is presented in Section E, below.

INDIRECT BUSINESS DISPLACEMENT DUE TO INCREASED RENTS

The preliminary assessment of indirect business displacement due to increased rents focuses on whether the proposed project could increase commercial property values and rents within the 3/4-mile study area so that it would become difficult for some categories of businesses to remain in the area. The following three questions (numbered in italics below) address the potential for significant adverse indirect business displacement impacts.

- 1. Would the proposed project introduce enough of a new economic activity or add to the concentration of a particular sector of the local economy enough to introduce trends that would alter existing economic patterns?*

The 3/4-mile study area contains a mix of economic activities. As shown in **Table 3-7**, in 2011, there were approximately 25,897 people employed at businesses located within the 3/4-mile perimeter that shapes the study area. The employees in the study area represent approximately 4.6 percent of the total employment in Queens. The accommodation and food services sector accounted for the largest proportion of employees in the study area (18.9 percent). This was more than twice the proportion of accommodation and food service employment in both Queens (9.0 percent) and New York City as a whole (8.7 percent).

Retail trade accounted for 15.2 percent of employment in the study area, which was slightly higher than in Queens (12.6 percent) and New York City (11.4 percent). Healthcare and social assistance accounted for 13.7 percent of employment in the study area, which was lower than the proportion of healthcare and social assistance employees in Queens (15.5 percent) but higher than in New York City as a whole (13.2 percent).

Table 3-7
Estimated Employees in ¾-Mile Study Area, Queens, and New York City
2011

Type of Job by NAICS Category	Study Area		Queens		New York City	
	Employees	Percent	Employees	Percent	Employees	Percent
Agriculture, forestry, fishing and hunting	1	0.0%	524	0.1%	1,595	0.0%

Source: ESRI Business Analyst Online, Inc., Business Summary Report						

The proposed project would result in a mix of uses by 2032, incorporating development substantially as anticipated and analyzed in the 2008 FGEIS and subsequent technical memoranda, as well as a major entertainment/retail component and parking adjacent to CitiField. Overall, the proposed project would include retail, entertainment, hotel, residential, community facility, and office uses; parking; a school; a convention center; and open space. The hotel, parking, community facility, office, convention center, and open space developments are not proposed to change from the program analyzed in the 2008 FGEIS and subsequent technical memoranda, and therefore are not considered in this assessment.

The proposed project would introduce approximately 1.4 million gsf (1.0 million sf of leasable area) of entertainment and retail uses as part of Willets West, which was not analyzed in the 2008 FGEIS and subsequent technical memoranda. This new retail development would be accompanied by a reduction in the overall amount of retail in the District, from 1.7 million gsf to 1.25 million gsf. As a result, the overall amount of retail and entertainment development would increase from 1.9 million gsf as analyzed in the 2008 FGEIS to 2.8 million gsf (2.4 million sf of leasable area).

As described in Chapter 1, "Project Description," Willets West would be developed on a portion of the surface parking lot west of CitiField. Willets West could include over 200 retail stores,

Willeys Point Development

including anchor and “mini” anchor retailers, as well as movie theaters, restaurant and food hall spaces, and entertainment venues. Surface parking and a parking structure also would be developed in this location, including 2,500 new spaces for the entertainment/retail center and 400 spaces of replacement parking for use by the Mets. In addition, by 2018 the westernmost CitiField surface parking lot south of Roosevelt Avenue (part of the South Lot) would be redeveloped as a structured parking facility, to replace a portion of the CitiField parking spaces formerly located on the Willets West portion of the project site. It is anticipated that this mass of retail uses would create a new destination, allowing for more comprehensive transit-oriented development around the Mets/Willeys Point stops on the No. 7 train and Long Island Rail Road. This development would serve as a catalyst for the subsequent build-out and economic development of the Willets Point area. Willets West would be created in Phase 1A of the proposed project, which is expected to be completed by 2018.

According to RPAD data, the $\frac{3}{4}$ -mile study area contains 5.3 million gsf of retail, and known projects in the study area are expected to add an estimated 660,320 gsf of additional retail space in the future without the proposed project. The 2.83 million gsf of retail and entertainment uses envisioned under the proposed project would be a substantial addition, but it would not be a new economic activity within the study area. Similarly, there are already destinations in the study area that offer entertainment and/or recreational opportunities, including Flushing Bay Promenade, CitiField, USTA National Tennis Center, Flushing Meadows-Corona Park, College Point Multiplex Theater, and Downtown Flushing.

There is already an established trend in the study area toward the development of retail, as evidenced by the several projects that have recently been completed, or are expected to be completed by 2032. Queens Crossing, a mixed-use development containing 110,000 gsf of retail space, was completed in 2007 on Main Street near the No. 7 subway station. Prince Plaza, a mixed-use development containing 72 residential units and 51,000 gsf of retail space, was completed in 2008, on Prince Street near 37th Avenue in Flushing. Sky View Center—part of the Sky View Parc development bounded by Whitestone Expressway, 40th Road, College Point Boulevard, and Roosevelt Avenue—is a major retail center with several large department and electronic stores, a supermarket, and a warehouse club. Flushing Commons, a planned mixed-use development including 275,000 gsf of retail, will be located between Main and Union Streets, north of 39th Avenue in Flushing. Given the existing established trend toward retail development within the study area, the increase in retail represents a continuation of an existing trend and would not change existing economic patterns in the study area.

According to RPAD data, as of 2012 the $\frac{3}{4}$ -mile study area contained an estimated 23,456 housing units. The study area already exhibits a strong trend toward residential development, including several large recently-completed projects such as Tower 3 of the Sky View Parc development, which added 448 market rate condominiums in Flushing. The 5,850 households that would be introduced by the proposed project would shop at some existing retail establishments, but would likely do a large portion of their shopping at the retail that would be introduced in the District. Therefore, it is not likely that the new households would substantially alter existing retail patterns in the study area.

Some industries or occupations tend to be considered more vulnerable than others to indirect displacement pressures. Businesses most vulnerable to indirect displacement due to increased rents are typically those businesses whose uses are less compatible with the economic trends that are creating upward rent pressures in the study area; i.e., those businesses that tend to not directly benefit in terms of increased business activity from the market forces generating the

increases in rent. For example, if a neighborhood is a more desirable place to live, uses that are less compatible with residential conditions (such as manufacturing) would be less able to afford increases in rent due to increases in property values compared with a neighborhood service use, such as a bank, which could see increased business activity from the increased residential presence.

Industrial uses within the study area would not capture any value from these customer trips, while a retail use could potentially capture additional sales from cross-shopping activity. Therefore, industrial uses in the study area could be considered vulnerable to indirect displacement, as a property owner could decide to convert an existing industrial property to a retail use. However, the possibility for this type of indirect displacement is limited by the underlying zoning. College Point and North Flushing are zoned for light manufacturing (M3-1 and M2-1, respectively), which limits the type and size of commercial retail uses without discretionary actions. Also, industrial uses include large municipal facilities, such as the New York City Department of Sanitation (DSNY) North Shore marine transfer station (MTS) in College Point. There are other prominent industrial uses in the study area, including the College Point Corporate Park, a 550-acre corporate park that includes large industrial businesses such as *The New York Times* printing and distribution plant, Skanska's North American headquarters, and Ares Printing and Packaging. The industrial uses on these properties would maintain the strong industrial character of the area.

The proposed project also would include a public school that would be approximately 100,000 gsf larger than analyzed in the FGEIS. This increment would not be larger enough to substantially alter economic trends in the study area, and therefore would not result in significant adverse impacts due to indirect business displacement.

2. Would the proposed project directly displace uses of any type that directly support businesses in the area or bring people to the area that form a customer base for local businesses?

The proposed project would result in the same direct displacement of uses as analyzed in the 2008 FGEIS; there are no businesses located on the portions of the project site outside the District. As described in the 2008 FGEIS, business establishments within the study area do not rely on District employees or visitors for their customer base, nor do business establishments in the study area rely on the products or services offered by District businesses. To the extent that products and services offered by District establishments may be utilized by businesses in the surrounding study area, these would still be available in the future with the proposed project in other areas of Queens and the City. Study area businesses do not require proximity to District businesses, and would not be adversely affected by the proposed project.

3. Would the proposed project directly or indirectly displace residents, workers, or visitors who form the customer base of existing businesses in the study area?

The proposed project would result in the same direct displacement as analyzed in the 2008 FGEIS, and the SEIS finds that the proposed project would result in similar levels of indirect displacement. As described in the 2008 FGEIS, the 1,711 employees directly displaced would represent approximately 4.0 percent of the employment in the study area, and the displacement of these employees would not represent a significant portion of the customer base for existing businesses. Furthermore, although the new residents, workers, and visitors would do the majority of their retail purchases in the District, it is likely that the existing retail businesses in the study area would capture a portion of their retail expenditures.

The proposed project is anticipated to generate approximately 3,671 employees. Similar to the new residents, while most of their spending would be in the proposed retail in the District, a portion would be captured by the retail in the study area. In addition, some project employees may live in the study area, increasing the likelihood that a larger proportion of their retail dollars would be spent at existing study area businesses. The influx of residents, employees, and visitors to the study area would create a sizable new customer base for existing and future retail services and businesses.

The preliminary assessment finds that the proposed project would not result in significant adverse socioeconomic impacts as a result of indirect business displacement due to increased rents. Therefore, detailed analysis of this issue is not warranted.

INDIRECT BUSINESS DISPLACEMENT DUE TO RETAIL MARKET SATURATION

Projects resulting in the development of large, regional-serving retail may draw sales from existing businesses in an area. According to the *CEQR Technical Manual*, this type of competitive pressure does not necessarily result in environmental impacts, especially in New York City, where increases in retail supply can usually be supported by high population density, population growth, visitor-generated sales, and overall purchasing power. However, competition can become an environmental concern if it has the potential to result in prolonged vacancy and disinvestment in neighborhood shopping areas, thereby affecting the character of the neighborhood.

The proposed project would result in the development of up to approximately 2.83 million gsf of retail and entertainment uses, including 1.4 million gsf (1.0 million sf of leasable area) on Willets West, 1.25 million gsf in the District, and 184,500 gsf on Lot B. This exceeds the 200,000-sf CEQR threshold for a preliminary assessment of indirect business displacement due to retail market saturation. For projects exceeding the 200,000-sf threshold, the *CEQR Technical Manual* prescribes a step-by-step preliminary assessment that can be described as a “capture rate analysis.” Capture rates are measures of business activity in a trade area, indicating the percentage of consumer expenditures for retail goods that are being captured by retailers in the trade area. If a capture rate exceeds 100 percent, then there is the potential for market saturation and a detailed analysis is required to determine whether the proposed project may capture retail sales from existing businesses to the extent that vacancies and disinvestment on neighborhood commercial streets would occur, thereby affecting land use patterns and the economic viability of the neighborhood.

CAPTURE RATE ANALYSIS

STEP 1

The first step in a retail capture rate analysis is to determine whether the categories of goods to be sold at the proposed development are similar to the categories of goods sold in stores found on neighborhood retail streets within the study area.

The proposed project would result in the development of up to approximately 2.83 million gsf of entertainment and retail uses, comprising a mix of local retail (i.e., small-scale stores geared towards serving the day-to-day needs of the study area population), and destination retail (i.e., retail generally sold in larger format stores that will attract customers from greater distances in order to compare price, quality, and the selection of merchandise), as well as movie theater, entertainment, and fitness uses.

Providers of business sales and household expenditure data do not typically consider entertainment and fitness-related uses to be retail and do not report data for those uses as part of their retail reports. Therefore, sales and expenditures related to the proposed project's 80,000 gsf movie theater and 400,000 gsf of entertainment and fitness uses are not included in the capture rate analysis presented below. The total amount of proposed project retail analyzed in this capture rate analysis is 1.95 million square feet.

Specific tenants and store sizes for the proposed project have not yet been determined. For purposes of this analysis, it is assumed that the retail program could include, in addition to various small and mid-size retail stores, two traditional department stores and one discount department store. Unlike the 2008 FGEIS, the SEIS does not assume that the proposed project would include wholesale clubs. The site planning for the District does not allow for the footprints and truck access necessary for a wholesale club format, and there are already numerous wholesale clubs within the neighborhoods surrounding the project site.

Nevertheless, with up to approximately 1.95 million gsf of retail excluding the proposed entertainment and fitness uses, it is assumed that the proposed project could include retailers whose product offerings do overlap with the offerings at some study area retail stores.

STEP 2

Step 2 in a retail capture rate analysis is to determine a Primary Trade Area. For the proposed "anchor" stores – the largest stores in the proposed development that are expected to yield the largest proportion of retail sales.

As described in the *CEQR Technical Manual*, an analysis of the potential effects of competition should encompass a primary trade area from which the bulk of new stores' sales are likely to be derived. According to the Urban Land Institute's *Shopping Center Development Handbook*, trade areas for shopping centers similar in size to the proposed project would generally extend 12 miles from the site, and typically can be reached within a 30-minute drive. However, trade areas for retail projects in New York City are typically smaller than the national standards cited in the *Shopping Center Development Handbook*, due primarily to the density of development in the New York metropolitan area. A 12-mile radius from the project site extends throughout Queens and into Brooklyn, Manhattan, and the Bronx, as well as Nassau County, NY; Hudson County, NJ; and Westchester County, NY. This would not be an appropriate trade area for the proposed project because many of those traveling from the more distant reaches of a 12-mile trade area would be traveling past destination retail concentrations of equal or greater size to reach the proposed project. For example, residents of Nassau County are more likely to regularly visit closer retail destinations such as Roosevelt Field Mall.

Therefore, for purposes of analysis, the Primary Trade Area for the proposed project is an adjusted five-mile perimeter around the project site (see **Figure 3-2**). The five-mile perimeter was adjusted to exclude the portions of Manhattan and the Bronx that fall within this area. The East River serves as a natural barrier between Queens and Manhattan and the Bronx, making the route from Manhattan and the Bronx to the project site less direct. Residents traveling by car via the Whitestone Bridge or the Midtown Tunnel would have to pay a toll to access the project site. Such factors would make it more convenient for households living in the Bronx and Manhattan to do their regular shopping in the boroughs in which they live. Thus, the Primary Trade Area excludes Manhattan and the Bronx and is roughly bounded by Long Island Sound on the north, the East River on the west, Alley Pond Park on the east, and Rockaway Boulevard on the south. The proposed project would likely draw a substantial number of customers from throughout

Willets Point Development

Queens because of the retail center's proximity to major roadways, its merchandise mix, and the regional attraction created by the 2.83 million gsf of retail and entertainment space.

STEP 3

Step 3 in the preliminary assessment is to estimate sales volumes for relevant retail stores within the Primary Trade Area, i.e., stores that sell categories of goods similar to those expected to be offered by stores introduced by the proposed project.

As described above, no specific retailing plan has been developed for the proposed project, but it is expected that the project would include retail stores selling a variety of goods and services. Therefore, this analysis assesses sales in three major retail categories: shoppers' goods; convenience goods; and eating and drinking establishments. Shoppers' goods are usually higher value goods—such as clothing, electronics, or furniture—for which consumers compare quality and price at more than one store before making a purchase. Convenience goods are usually lower value goods that are purchased frequently and immediately, often near the home or workplace, with little or no comparison shopping. The eating and drinking establishment category includes restaurants, bars, and other special food services, such as caterers.

Data for department stores and grocery stores—subsets of the shoppers' goods and convenience goods categories, respectively—are also analyzed. This analysis focuses on these stores in particular because grocery stores and department stores often serve as anchors for retail concentrations, and the proposed project could introduce stores offering products that would substantially overlap with typical grocery store or department store offerings.

According to ESRI, a national provider of geographic planning data, retail sales at stores in the Primary Trade Area totaled approximately \$5.9 billion in 2010 for the retail categories analyzed (see **Table 3-8**). Approximately 31 percent of these sales were at shoppers' goods stores (\$1.9 billion), 47 percent at convenience goods stores (\$2.8 billion), and 22 percent at eating and drinking establishments (\$1.3 billion). Only six percent of sales in the shoppers' goods category were attributed to department stores (\$114.2 million), reflecting the prevalence of small- and mid-size stores rather than larger-format department stores in the Primary Trade Area.

Table 3-8
Retail Sales in the Primary Trade Area

Retail Category	Total Sales (Millions of 2012 Dollars)
Shoppers' Goods ¹	\$1,855.79
Department Stores	\$114.23
Convenience Goods ¹	\$2,774.88
Grocery Stores	\$1,697.29
Eating and Drinking Establishments	\$1,318.07
Total²	\$5,948.74
Notes: 1. Shoppers' Goods include: furniture and home furnishings stores; electronics and appliance stores; clothing and clothing accessories stores; sporting goods, hobby, book, and music stores; general merchandise stores; office supply, stationary, and gift stores; and used merchandise stores. Convenience Goods include: food and beverage stores; health and personal care stores; florists; and other miscellaneous store retailers. 2. Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.	
Sources: ESRI, Inc.; AKRF, Inc.	

STEP 4

Step 4 in the preliminary assessment is to estimate the expenditure potential, or retail demand, for relevant retail goods of shoppers within the Primary Trade Area.

Retail demand for any retail concentration can originate from a variety of sources, including local households and workers, businesses, tourists, and online sales. Data sources that report on both retail demand and sales tend to focus on demand from households in a defined geography and do not always address demand from workers, businesses, or tourists, which can be more difficult to pinpoint and relate directly to retail sales. (The U.S. Census Bureau compiles data on household expenditures by retail category, but does not have a corresponding data set for spending by workers or tourists for defined geographies, and many data providers rely heavily on information from the U.S. Census Bureau.) The data sets available for this analysis provide retail demand estimates only for Primary Trade Area households, not for workers, tourists, or other visitors who live outside of the Primary Trade Area, and therefore do not capture the true magnitude of expenditure potential within the trade area. This underestimate of expenditure potential for a trade area typically results in capture rates that are conservatively high.

According to ESRI, households in the Primary Trade Area spent an estimated \$9.7 billion on retail goods in 2010 (see **Table 3-9**).¹ Approximately 32 percent was spent on shoppers' goods, 43 percent on convenience goods, and 25 percent on eating and drinking establishments. On a per household basis, Primary Trade Area residents spent roughly \$5,118 annually on shoppers' goods including an estimated \$458 at department stores, \$6,909 annually on convenience goods including \$4,570 at grocery stores, and \$3,988 on eating and drinking establishments.

Table 3-9
Retail Demand of Households in the Primary Trade Area

	Total Demand (Millions of 2012 Dollars) ¹	Demand per Household (2012 Dollars) ¹
Shoppers' Goods ²	\$3,115.49	\$5,118
<i>Department Stores</i>	\$278.70	\$458
Convenience Goods ²	\$4,205.86	\$6,909
<i>Grocery Stores</i>	\$2,781.73	\$4,570
Eating and Drinking Establishments	\$2,427.84	\$3,988
Total³	\$9,749.18	\$16,016
Notes: 1. Demand (retail expenditure potential) estimates the expected amount spent by consumers at retail establishments. 2. Shoppers' Goods include: furniture and home furnishings stores; electronics and appliance stores; clothing and clothing accessories stores; sporting goods, hobby, book, and music stores; general merchandise stores; office supply, stationary, and gift stores; and used merchandise stores. Convenience Goods include: food and beverage stores; health and personal care stores; florists; and other miscellaneous store retailers. 3. Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.		
Sources: ESRI, Inc.; AKRF, Inc.		

¹ If retail expenditure of workers, tourists or other visitors were added to this figure, total retail demand in the Primary Trade Area would likely well exceed \$9.75 billion.

STEP 5

Step 5 in the preliminary assessment is to compare retail sales (Step 3) with retail demand (Step 4) to develop a “capture rate,” which can help determine whether the Primary Trade Area is currently saturated with retail uses or whether there is likely to be an outflow of sales from the area.

Capture rates are measures of business activity in a trade area, indicating the percentage of consumer expenditures for retail goods that are being captured by retailers in the trade area. If the total sales in the trade area are much lower than the area’s household expenditure potential, then residents are likely spending a large portion of their available dollars outside of the trade area, and the capture rate is low. If sales are closer in value to expenditure potential, then area residents are likely spending a higher proportion of their available resources within the area, and the capture rate is high.

Capture rates are also affected by money flowing into an area from people who do not live in that area. Some of the sales in the Primary Trade Area, for example, are from people living in other areas of Manhattan, other New York City boroughs, Nassau County, NY, Hudson County, NJ and elsewhere, shopping at stores in the Primary Trade Area. However, it is not possible to know exactly who (residents or nonresidents) is spending money in the area. Therefore, a high capture rate may be indicative of an area with a high proportion of destination retail, i.e., retail that will attract customers from greater distances in order to compare price, quality, and the selection of merchandise. This is the case for New York City as a whole, where the retail capture rate is approximately 109 percent and the capture rate for shopper’s goods is 138 percent. Despite these uncertainties about the origin of sales in any particular trade area, comparing expenditure and sales data can provide a good indication of how much of a trade area’s household expenditure potential is being captured by trade area retailers.

Tables 3-10 through 3-12 show the capture rates for the Primary Trade Area, Queens, and New York City. As indicated above, these capture rates are conservative in that they include sales to all households, regardless of where they live, but they only include expenditures from households living within the geography being analyzed. As shown in **Table 3-10**, total retail sales for shoppers’ goods, convenience goods, and eating and drinking establishments in the Primary Trade Area were approximately \$5.95 billion in 2010. Potential retail expenditures for these goods, on the other hand, were \$9.75 billion, indicating that retail stores in the Primary Trade Area are capturing only 61 percent of the Primary Trade Area household expenditure potential. This indicates that Primary Trade Area residents are making a substantial portion of their retail purchases outside of the area, which may include other portions of Queens, other boroughs, and very likely Nassau County. In comparison, the retail capture rate for these retail categories for New York City was 114 percent. As shown in **Table 3-12**, the high overall capture rate for New York City is attributable primarily to shoppers’ goods sales, which has a capture rate of 143 percent. This suggests that shoppers’ goods stores in the City are likely capturing a high percentage of available household expenditure potential, plus additional spending from people who live outside of the City, including day-trippers, but also overnight visitors from outside the metropolitan area, including national and international visitors.

Table 3-10
Household Retail Expenditures and Total Retail Sales, Primary Trade Area, 2010

	Retail Sales in Primary Trade Area ¹	Retail Demand from Primary Trade Area Households ¹	Amount Not Being Captured in Primary Trade Area ¹	Primary Trade Area Capture Rate
Shoppers' Goods	\$1,855.79	\$3,115.49	\$1,259.70	60%
<i>Department Stores</i>	\$114.23	\$278.70	\$164.47	41%
Convenience Goods	\$2,774.88	\$4,205.86	\$1,430.98	66%
<i>Grocery Stores</i>	\$1,697.29	\$2,781.73	\$1,084.45	61%
Eating and Drinking Establishments	\$1,318.07	\$2,427.84	\$1,109.77	54%
Total²	\$5,948.74	\$9,749.18	\$3,800.44	61%
Notes: 1. All values are in millions of 2012 dollars. 2. Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.

Table 3-12
Household Retail Expenditures and Total Retail Sales, New York City, 2010

	Retail Sales in Primary Trade Area ¹	Retail Demand from Primary Trade Area Households ¹	Amount Not Being Captured in Primary Trade Area ¹	Primary Trade Area Capture Rate
Shoppers' Goods	\$24,769.56	\$17,326.90	(\$7,442.66)	143%
<i>Department Stores</i>	\$1,199.10	\$1,378.76	\$179.66	87%
Convenience Goods	\$19,820.28	\$22,724.82	\$2,904.54	87%
<i>Grocery Stores</i>	\$1,515.43	\$2,059.49	\$544.06	74%
Eating and Drinking Establishments	\$16,793.81	\$13,716.33	(\$3,077.48)	122%
Total²	\$61,383.64	\$53,768.05	(\$7,615.59)	114%
Notes: 1. All values are in millions of 2012 dollars. 2. Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.				
Sources: ESRI, Inc; AKRF, Inc.				

STEP 6

Step 6 in the preliminary assessment is to assess factors that will affect conditions in the Primary Trade Area in the build year even absent the proposed project. Such factors typically include population changes, which could increase expenditure potential and generate additional demand for retail goods, and new retail projects, which would expand the retail inventory.

The primary changes that may affect retail market conditions in the Primary Trade Area in the future without the proposed project are population changes, which could increase expenditure potential and generate additional demand for retail goods, as well as new retail projects, which would expand the retail inventory

Based on research on projects either planned or currently under construction within an approximately 1-mile radius of the project site, the Primary Trade Area will gain 2,706 housing units, all by 2018. Outside of the 1-mile area, there are no significant residential projects known to be planned or under construction within the Primary Trade Area. With the 2,706 new households in place, the Primary Trade Area will contain approximately 611,439 households. As shown in **Table 3-9**, Primary Trade Area households currently spend approximately \$16,016 per year on the three retail categories highlighted in this analysis. If the additional households continue to spend the same amount per year, the households would increase the retail demand by \$43.34 million. These households would spend approximately \$13.85 million on shoppers' goods (including \$1.24 million at department stores), \$18.70 million on convenience goods (including \$12.37 million at grocery stores), and \$10.79 million at eating and drinking establishments.

Thus, the total household expenditure potential for retail goods—including the additional households anticipated in the No Action condition—will be approximately \$9.8 billion in the future without the proposed project by 2032.

At the same time, retail sales in the Primary Trade Area will also increase as new retail projects are completed. Based on research on projects either planned or currently under construction within 1 mile of the proposed project site, and an additional search for substantial retail projects in the broader Primary Trade Area, there are 30 retail projects expected to be completed in the Primary Trade Area over the next several years. These projects would add approximately 851,300 gsf of retail space to the Primary Trade Area. Based on sales per square foot estimates obtained from *Dollars & Cents of Shopping Centers, 2008*, the stores would have annual sales of approximately \$469 million, increasing total trade area retail sales by approximately 7.9 percent, from \$5.95 billion to \$6.42 billion by 2032 (in constant 2012 dollars).

As shown in **Table 3-13**, with annual sales of approximately \$6.51 billion and household expenditure potential of \$9.81 billion, the capture rate for the Primary Trade Area will be approximately 66 percent in the future without the proposed project by 2032, five percentage points higher than under existing conditions.

Table 3-13
2032 No Action Condition:
Household Retail Expenditures and Total Retail Sales, Primary Trade Area

	Retail Sales in Primary Trade Area ^{1,2}	Retail Demand from Primary Trade Area Households ¹	Amount Not Being Captured in Primary Trade Area ¹	Primary Trade Area Capture Rate
Shoppers' Goods	\$2,090.76	\$3,134.34	\$1,043.58	67%
<i>Department Stores</i>	\$114.23	\$280.39	\$166.16	41%
Convenience Goods	\$3,045.45	\$4,231.31	\$1,185.86	72%
<i>Grocery Stores</i>	\$1,885.29	\$2,798.57	\$913.28	67%
Eating and Drinking Establishments	\$1,370.96	\$2,442.53	\$1,071.57	56%
Total³	\$6,507.18	\$9,808.18	\$3,301.00	66%
Notes: 1. All values are in millions of 2012 dollars. 2. A number of the projects known to be planned or under construction in the Primary Trade Area cite "commercial" uses without specifying whether the commercial space would be office or retail. This analysis conservatively assumes all general "commercial" uses to be retail. 3. Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.				
Sources: ESRI, Inc; AKRF, Inc.				

STEP 7

Step 7 is to project the sales volume for the proposed project's retail uses.

As described above under Step 1, the proposed project would introduce up to approximately 1.95 million gsf of analyzed retail, including both destination and local (neighborhood-oriented) retail, as well as an 80,000 square foot movie theater and 400,000 square feet of entertainment and fitness uses. **Table 3-14** shows the breakdown of retail assumed under this analysis, broken out by development phase. Phase 1A would include 920,000 gsf of enclosed retail on the Willets West site,¹ as well as 30,000 square feet of retail in the District. The Phase 1A District retail is currently anticipated to be comprised of approximately 15,000 square feet of neighborhood retail and 15,000 square feet of food and beverage stores. For the purposes of this analysis, the retail planned for Willets West is anticipated to include two traditional department stores as anchor tenants, 35,000 square feet of specialty food stores, 10,000 square feet of food court, and 90,000 square feet of other restaurant and café space, with the remaining 485,000 square feet occupied by a mix of inline tenants offering a range of shoppers' goods.

The remainder of the District would be built out during Phase 1B and Phase 2 with 820,000 square feet of retail space, as well as the other uses detailed above. It is currently anticipated that approximately 444,500 square feet of this retail space would be occupied by convenience goods stores, 325,500 square feet by shoppers' good stores, and 50,000 square feet by eating and drinking establishments. For purposes of analysis, it is assumed that Phase 1B would include a 115,000-square-foot discount department store offering both shoppers' goods and grocery items.

The reasonable worst-case development scenario assumes that by 2032, consistent with the assumptions of the 2008 FGEIS, Lot B would be developed with an additional 184,000 square feet of retail including a mix of shoppers' goods and eating and drinking establishments.

¹ In addition to retail uses, the Willets West site is anticipated to include an 80,000-square-foot movie theater as part of Phase 1A, and Phase 1B is anticipated to include 400,000 square feet of entertainment and fitness uses.

Table 3-14

Proposed Project Retail Program by Development Phase

Retail Categories	2018/Phase 1A ⁽¹⁾		2028/Phase 1B ⁽¹⁾	2032/Phase 2		TOTAL (GSF)
	Willets West (GSF)	District (GSF)	District (GSF)	District (GSF)	Lot B (GSF)	
Shoppers Goods	785,000	0	257,500	68,000	134,000	1,244,500
Discount Department Store ⁽²⁾	0	0	80,500	0	0	80,500
Department Store	300,000	0	0	0	0	300,000
All Other	485,000	0	177,000	68,000	134,000	864,000
Convenience Goods	35,000	15,000	167,500	277,000	0	494,500
Grocery at Discount Department Store ⁽²⁾	0	0	34,500	0	0	34,500
Specialty Food at Destination Retail	35,000	0	0	0	0	35,000
Grocery at Neighborhood Retail	0	0	45,000	35,000	0	80,000
Other Neighborhood Retail ⁽³⁾	0	15,000	88,000	242,000	0	345,000
Eating and Drinking	100,000	15,000	50,000	0	50,000	215,000
Destination Retail - Restaurants	90,000	0	10,000	0	50,000	150,000
Destination Retail - Food Court	10,000	0	0	0	0	10,000
Neighborhood Retail	0	15,000	40,000	0	0	55,000
Total⁽⁴⁾	920,000	30,000	475,000	345,000	184,000	1,954,000
Notes: (1) In addition to the uses listed above, Phase 1A is anticipated to include an 80,000 square foot movie theater, and Phase 1B is anticipated to include 400,000 square feet of entertainment and fitness uses. Sales from the movie theater and entertainment and fitness uses were not included in this analysis. (2) Based on information from selected SEC 10-K filings of typical discount department stores, approximately 30 percent of sales at the discount department store are assumed to be from grocery items (3) Conservatively includes all neighborhood service businesses (e.g., laundromat, nail and hair salons, etc.) (4) Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.						
Sources: Total retail square footage by development phase was provided by the Queens Development Group, LLC (QDG). Breakdown of retail square footage by broad retail category was developed by AKRF, Inc. with input from QDG for purposes of a reasonable worst-case analysis under CEQR.						

As shown in **Table 3-15**, by 2032 retail sales resulting from the proposed project are projected to be approximately \$1.07 billion annually (in 2012 dollars), generated by approximately 1.24 million square feet of shoppers' goods space, 494,500 square feet of convenience goods space, and 215,000 square feet of eating and drinking establishments. Annual sales for shoppers' goods are estimated at \$541.5 million; annual sales for convenience goods are estimated to be \$311.7 million; and annual sales for eating and drinking establishments are estimated to be \$221.5 million.

The approximately \$1.07 billion in projected retail sales from the proposed project would represent 17 percent of total retail sales for the Primary Trade area in the future without the proposed project, which are estimated to be \$6.42 billion annually.

The proposed actions would also introduce 5,850 residential units to the Primary Trade Area by 2032. Based on 2010 retail expenditure estimates from ESRI, these households would add approximately \$93.7 million to the trade area expenditure potential (see **Table 3-16**).

Table 3-15

Estimated Retail Sales at Stores Introduced Under the RWCDs

	Square Feet	Total Sales (Millions of 2012 Dollars)
Shoppers Goods	1,244,500	\$ 541.53
Discount Department Store	80,500	\$28.98
Department Store	300,000	\$81.27
All Other	864,000	\$431.28
Convenience Goods	494,500	\$ 311.68
Grocery at Discount Department Store	34,500	\$12.42
Specialty Food at Destination Retail	35,000	\$34.36
Grocery at Neighborhood Retail	80,000	\$55.89
Other Neighborhood Retail ⁽¹⁾	345,000	\$209.01
Eating and Drinking	215,000	\$221.53
Destination Retail – Restaurants	150,000	\$172.73
Destination Retail - Food Court	10,000	\$15.01
Neighborhood Retail	55,000	\$33.79
Total⁽²⁾	1,954,000	\$ 1,074.74
Notes: (1) Conservatively includes all neighborhood service businesses (e.g., laundromat, nail and hair salons, etc.) (2) Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included. Sources: Discount department store sales were estimated based on per square foot sales figures obtained from 10-K filings of typical discount department stores. Sales for all other shoppers' goods, convenience goods, and eating and drinking establishments were estimated based on data from the Urban Land Institute's 2008 Dollars and Cents of Shopping Centers.		

Table 3-16

**Estimated Retail Demand from Households
to be Introduced by Proposed Project by 2032**

	Retail Demand from Households⁽¹⁾
Shoppers' Goods	\$29.34
<i>Department Stores</i>	<i>\$2.69</i>
Convenience Goods	\$40.62
<i>Grocery Stores</i>	<i>\$26.88</i>
Eating and Drinking Establishments	\$23.43
Total⁽²⁾	\$93.69
Notes: (1) Values are in millions of 2012 dollars. (2) Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included. Sources: ESRI, Inc; AKRF, Inc.	

STEP 8

Step 8 is to develop a capture rate for the Primary Trade Area in the future with the proposed project. According to the CEQR Technical Manual, if the capture rate for relevant categories of goods would exceed 100 percent, it may have the potential to saturate the market for particular retail goods and a detailed assessment is warranted.

As described above under Step 7, by 2032 the proposed project would increase retail sales in the Primary Trade Area by an estimated \$1.07 billion annually (in 2012 dollars), and by 2032 would increase household retail expenditure potential by approximately \$93.69 million annually (in

2012 dollars). **Table 3-17** compares Primary Trade Area retail sales, demand, and capture rates for existing conditions and in the future with the proposed actions by 2032.

Table 3-17

**Comparison of Estimated Retail Capture Rates in Primary Trade Area:
Existing Conditions, Future Without the Proposed Project
and Future With the Proposed Project in 2032**

	Retail Sales in Primary Trade Area ⁽¹⁾	Retail Demand from Primary Trade Area Households ⁽¹⁾	Primary Trade Area Capture Rate ⁽¹⁾
Existing Conditions			
Shoppers' Goods	\$1,855.79	\$3,115.49	60%
<i>Department Stores</i>	\$114.23	\$278.70	41%
Convenience Goods	\$2,774.88	\$4,205.86	66%
<i>Grocery</i>	\$1,697.29	\$2,781.73	61%
Eating and Drinking	\$1,318.07	\$2,427.84	54%
TOTAL	\$5,948.74	\$9,749.18	61%
2032 Without the Proposed Project			
Shoppers' Goods	\$2,090.76	\$3,134.34	67%
<i>Department Stores</i>	\$114.23	\$280.39	41%
Convenience Goods	\$3,045.45	\$4,231.31	72%
<i>Grocery</i>	\$1,885.29	\$2,798.57	67%
Eating and Drinking	\$1,370.96	\$2,442.53	56%
TOTAL	\$6,507.18	\$9,808.18	66%
2032 With the Proposed Actions			
Shoppers' Goods	\$2,632.30	\$3,164.28	83%
<i>Department Stores</i>	\$224.48	\$283.06	79%
Convenience Goods	\$3,357.13	\$4,271.73	79%
<i>Grocery</i>	\$1,987.95	\$2,825.30	70%
Eating and Drinking	\$1,592.49	\$2,465.86	65%
TOTAL(2)	\$7,581.91	\$9,901.87	77%
Notes: (1) All values are in millions of 2012 dollars. (2) Total does not reflect total for all retail—only those retail categories included in Shoppers' Goods, Convenience Goods, and Eating and Drinking Establishments. Retail establishments not included in this total are: Auto-Related Businesses, Building Materials and Garden Supply, and Non-Store Retailers. Entertainment and fitness uses also are not included.			
Sources: ESRI, Inc.; AKRF, Inc.			

As shown in the table, by 2032 the overall retail capture rate would increase to 77 percent in the future with the proposed project. This capture rate is approximately 11 percentage points higher than in the future without the proposed project (2032). The shoppers' goods category would experience the greatest relative increase, with the capture rate increasing from 67 percent in the future without the proposed project to 83 percent in the future with the proposed project. The capture rate for the department store subset of shoppers' goods would increase from 41 percent to 79 percent. Increases for the other categories would be more modest, with the grocery store capture rate increasing by three percentage points to 70 percent and the eating and drinking establishment capture rate increasing by nine percentage points to 65 percent.

Based on *CEQR Technical Manual* guidelines, if the capture rate for specific, relevant categories of goods would exceed 100 percent in the future with the proposed project, it may have the potential to saturate the market for particular retail goods and a detailed analysis is warranted. As shown above, capture rates for each of the retail categories analyzed would remain below 100 percent in the future with the proposed project. Therefore, this preliminary assessment finds that the proposed project would not have the potential to saturate the market for particular retail goods. Based on *CEQR Technical Manual* methodology, if capture rates with the proposed

project do not exceed 100 percent, then a detailed analysis is not warranted. However, in order to maintain a consistent scope of analysis as performed for the FGEIS, a detailed analysis is provided in section F, below, even though it is not warranted pursuant to *CEQR Technical Manual* guidelines.

F. DETAILED ANALYSIS OF INDIRECT RESIDENTIAL DISPLACEMENT

The preliminary assessment for indirect residential displacement in Section E, above, indicated the need for further analysis in order to determine whether the proposed project could result in significant adverse impacts due to indirect residential displacement. Therefore, a detailed analysis has been conducted. The approach to a detailed analysis of indirect residential displacement builds upon the information provided in the preliminary assessment, but requires more in-depth analysis of census information and includes field surveys. The objective of the detailed analysis is to determine whether the proposed project may introduce or accelerate a socioeconomic trend that may potentially displace a vulnerable population (“population at risk”). Populations at risk are defined as renters living in units not protected by rent stabilization, rent control, or other government regulations restricting rents, whose incomes are too low to afford increases in rents.

In order to determine potential impacts, the detailed analysis characterizes existing conditions of residents and housing and identifies any existing populations that are potentially at risk of indirect residential displacement. The analysis then assesses current and future socioeconomic trends in the area that may affect these populations, and examines the potential effects of the proposed project on those trends.

The detailed analysis uses the $\frac{3}{4}$ -mile study area used in the preliminary assessment of indirect residential displacement. As in the preliminary assessment, the area was modified to conform to census tract boundaries (see **Figure 3-1**). The resulting study area includes the subareas of College Point, Corona, and Greater Flushing.¹ The data are presented for the $\frac{3}{4}$ -mile study area, the subareas, and for individual census tracts, where appropriate.

EXISTING CONDITIONS

This section describes the population and housing characteristics of the $\frac{3}{4}$ -mile study area. It outlines trend data since 2000, and compares the characteristics of the $\frac{3}{4}$ -mile study area to Queens and New York City.

POPULATION

According to the U.S. Census, in 2010 the $\frac{3}{4}$ -mile study area had a population of 91,156 residents (see **Table 3-18**). The residential population grew by approximately 10.4 percent since 2000, which is a higher rate of growth than in Queens during the same time period (0.1 percent),

¹ The 2008 FEIS included three areas within the Greater Flushing subarea—North Flushing, Downtown Flushing, and South Flushing. Due to changes in census tract boundaries since 2000, these areas were combined into one Greater Flushing subarea for this SEIS. In addition, the 2010 Census boundaries for the Corona subarea include an additional small area to the east of the 2000 Census boundaries used in the 2008 FGEIS. This additional area includes only landscaped grounds bordering Grand Central Parkway, and does not contain any residential units or businesses.

Willeys Point Development

as well as New York City as a whole (2.1 percent). The Corona subarea, comprising the portion of the study area west of the project site between Flushing Bay and Corona Avenue, experienced the highest population growth between 2000 and 2010, with a 16.7 percent increase. This is due to a combination of new residential development within the subarea and an increase in the average household size (see **Table 3-19**). College Point, which is a largely industrial and commercial area, has the lowest residential population within the study area, and it experienced a relatively low rate of population growth between 2000 and 2010.

Table 3-18
Population Change 2000 to 2010

Area	Population		Percent Change
	2000	2010	
Study Area	82,573	91,156	10.4%
College Point	1,354	1,355	0.1%
Corona	39,574	46,175	16.7%
Greater Flushing	41,645	43,626	4.8%
Queens County	2,229,379	2,230,722	0.1%
New York City	8,008,278	8,175,133	2.1%
Sources: U.S. Department of Commerce, Bureau of the Census, 2000 and 2010 Census Summary File 1; AKRF, Inc.			

HOUSEHOLDS AND INCOME

According to the U.S. Census, the $\frac{3}{4}$ -mile study area contained a total of 27,965 households in 2010, with an average household size of 3.24 persons per household (See **Table 3-19**). This is higher than the average household size for both Queens and New York City as a whole. The increase in household size in the $\frac{3}{4}$ -mile study area is reflected in the percent change in total households between 2000 and 2010 (5.9 percent), which was lower than the corresponding increase in population (10.4 percent). The Corona subarea had the largest overall, and percent increase in, average household size over this time, with 3.83 persons per household in 2000 and 4.14 persons per household in 2010.

Table 3-19
Household Characteristics: 2000 and 2010

	Total Households			Average Household Size		
	2000	2010	Percent Change	2000	2010	Percent Change
Study Area	26,417	27,965	5.9%	3.11	3.24	4.3%
College Point	471	448	-4.9%	2.87	3.02	5.2%
Corona	10,301	11,103	7.8%	3.83	4.14	8.0%
Greater Flushing	15,645	16,414	4.9%	2.64	2.64	0.0%
Queens County	782,664	780,117	-0.3%	2.81	2.82	0.4%
New York City	3,021,588	3,109,784	2.9%	2.59	2.57	-0.8%
Sources: U.S. Department of Commerce, Bureau of the Census, 2000 and 2010 Census Summary File 1; AKRF, Inc.						

The preliminary assessment presents the average household income for the study area, Queens, and New York City (see **Table 3-4**). According to 2007-2011 ACS data, the average household income for the study area was \$46,846. This was lower than the average household income in Queens (\$58,893) and in New York City as a whole (\$53,530) during the same time. Average household income decreased in the study area by 3.5 percent between 1999 and 2007-2011.

Over that same time period, average household income decreased in Queens and New York City as a whole, by 2.3 percent and 1.6 percent, respectively.

Based on 2007-2011 ACS data, median household income in the study area was \$48,846—a decrease of approximately 3.5 percent since 1999 (See **Table 3-20**). Both Queens and New York City as whole experienced decreases in median household income over this time (2.3 percent and 1.6 percent, respectively). The decrease in the study area median household income is due to decreased household incomes in College Point (of 27.4 percent) and in Greater Flushing (of 6.3 percent). In Corona, median household income increased during this time, by 1.2 percent.

Table 3-20
Income Characteristics and Trends

Area	Median Household Income ¹			Poverty Status (Percent) ²	
	1999	2007-2011	Percent Change	1999	2007-2011
Study Area	\$48,563	\$46,846	-3.5	22.2	21.3
College Point	\$65,295	\$47,399	-27.4	12.5	14.4
Corona	\$49,988	\$50,607	1.2	23.6	22.2
Greater Flushing	\$47,213	\$44,254	-6.3	21.1	20.5
Queens County	\$60,298	\$58,893	-2.3	14.6	13.7
New York City	\$54,407	\$53,530	-1.6	21.2	19.4
Notes: 1. Median household income is presented in constant 2012 dollars based on the U.S. Department of Labor Bureau of Labor Statistics' 2012 half-year average Consumer Price Index for all Urban Consumers for New York-Northern New Jersey-Long Island. Median household income for the subareas and the study area represents a weighted average of the median incomes of the census tracts in the subareas or study area. 2. Percent of population with incomes below established poverty level. The Census Bureau uses a set of money income thresholds that vary by family size and composition to detect who is in poverty. If the total income for a family or unrelated individual falls below the relevant poverty threshold, then the family or unrelated individual is classified as being "below the poverty level." The official poverty thresholds do not vary geographically, but they are updated annually for inflation using the Consumer Price Index.					
Sources: U.S. Department of Commerce, Bureau of the Census, 2000 Census, Summary File 1 and Summary File 3; American Community Survey 2007-2011 5-Year Estimates; U.S. Department of Labor Bureau of Labor Statistics' Consumer Price Index for all Urban Consumers for New York-Northern New Jersey-Long Island.					

The proportion of the population in the study area living below the poverty level has decreased since 1999, from 22.2 percent of the study area population for whom poverty status is determined, to 21.3 percent in 2007-2011 (see **Table 3-20**). Unlike the other subareas, College Point experienced an increase in the proportion of its population living below the poverty level, from 12.5 percent of the population to 14.4 percent.

HOUSING

As shown in **Table 3-21**, the total number of housing units in the study area increased roughly in line with the population increase between 2000 and 2010. The number of housing units in the study area increased by 14.1 percent during this time, compared with a 2.2 percent increase in Queens and a 5.3 percent increase in New York City. Within the study area, Corona and Greater Flushing experienced the largest increases (13.0 percent and 15.3 percent, respectively), while total housing units in College Point declined by 2.1 percent. The 2010 estimated vacancy rate for the study area was greater than in 2000; vacancies increased from 3.6 percent in 2000 to 10.6 percent in 2010, with the largest increase in the Greater Flushing subarea.

Table 3-21
Housing Characteristics and Trends

Area	Total Housing Units			Occupancy Status (Percent)				Tenure (Percent)			
	2000	2010	Percent Change	Occupied		Vacant		Owner		Renter	
				2000	2010	2000	2010	2000	2010	2000	2010
Study Area	27,403	31,269	14.1	96.4	89.4	3.6	10.6	28.0	29.0	72.0	71.0
College Point	485	475	-2.1	97.1	94.3	2.9	5.7	57.5	51.3	42.5	48.7
Corona	10,768	12,170	13.0	95.7	91.2	4.3	8.8	25.0	23.3	75.0	76.7
Greater Flushing	16,150	18,624	15.3	96.9	88.1	3.1	11.9	29.0	32.2	71.0	67.8
Queens County	817,250	835,127	2.2	95.8	93.4	4.2	6.6	42.8	43.0	57.2	57.0
New York City	3,200,912	3,371,062	5.3	94.4	92.2	5.6	7.8	30.2	31.0	69.8	69.0

Sources: U.S. Department of Commerce, Bureau of the Census, 2000 Census, Summary File 3.

The study area has a higher percentage of renters than in Queens and New York City; approximately 71.0 percent of the study area's residential units are renter-occupied, compared with 57.0 percent and 69.0 percent in Queens and New York City, respectively. Study area renters are most concentrated in Corona and Greater Flushing, where they account for 76.7 and 67.8 percent of occupied units, respectively. In contrast, in College Point, renters accounted for 48.7 percent of occupied housing units in 2010, and home-owners accounted for 51.3 percent. In the study area, Queens, and New York City, home ownership has increased slightly since 2000.

As shown in **Table 3-22**, according to 2007-2011 ACS data the median home value in the study area was \$386,553, which is lower than in Queens (\$494,897) and in New York City as a whole (\$537,600). Though median home values are lower in the study area than in Queens and New York City as a whole, home values have increased by 87.1 percent in the study area since 2000, as compared with 68.9 percent and 71.1 percent increases in Queens and New York City, respectively, during the same period. Within the study area, median home values increased in all of the subareas since 2000, with the greatest increase experienced in Greater Flushing (149.5 percent).

Table 3-22
Median Home Value and Contract Rent

	Median Home Value			Median Contract Rent ¹		
	2000	2007-2011	Percent Change	2000	2007-2011	Percent Change
Study Area	\$206,602	\$386,553	87.1%	\$1,044	\$1,209	15.8%
College Point	\$358,896	\$548,981	53.0%	\$941	\$988	5.0%
Corona	\$344,061	\$553,226	60.8%	\$1,065	\$1,340	25.9%
Greater Flushing	\$119,379	\$297,854	149.5%	\$1,036	\$1,112	7.4%
Queens County	\$292,971	\$494,897	68.9%	\$1,024	\$1,185	15.7%
New York City	\$314,283	\$537,600	71.1%	\$918	\$1,055	14.9%

Notes: Median contract rent for study area based on weighted median contract rent for all census tracts for which data was available, using all renter-occupied units for weights, not specified renter-occupied housing units paying cash rent.

Source: American Community Survey 2007-2011 5-Year Estimates.

Based on 2007-2011 ACS data, median contract rent in the study area is an estimated \$1,209 per month, which represents a 15.8 percent increase since 2000. The percent increase in study area median contract rent was slightly higher than experienced in Queens and New York City as a whole. Within the study area, median contract rent increased by the highest percentage in

Corona (25.9 percent), to \$1,340 per month from 2007-2011. This was the highest in the study area, and higher than in Queens and New York City as a whole during the same time period.

RECENT RESIDENTIAL TRENDS

Recent listings on real estate and brokerage websites indicate that median sales prices in the College Point and Flushing subareas were higher than for Queens as a whole, while the median sales price for the Corona subarea was lower than for Queens as a whole. According to recent listings on Streeteasy.com and Elliman.com, the median sales price for residential units in Queens was \$364,949. The median sales price in Corona was \$349,500, slightly lower than the borough median. College Point had a median sales price of \$564,500, and Flushing had a median sales price of \$682,500, both higher than the median sales price for Queens. These median sales prices differ from the median homes values reported in ACS data. As ACS median home value data reports what respondents' estimate their properties would sell for, this discrepancy may reflect the changing nature of the residential market and the perception of the market in these areas, with large new developments skewing listings and smaller, older residential buildings lowering the median. These higher market-rate listings are due to recent residential developments in the study area, primarily in Flushing. In Flushing, Tower 3 of the Sky View Parc development added 448 market rate apartments, which have sold at an average of \$621,000.¹

Listings of market-rate rental rates were generally higher than the median contract rents reported in ACS data, and median rental rates were lower than medians for the same number of bedrooms in Queens and New York City as a whole. A survey of current market-rate rentals in College Point found that average rental rates for one-bedroom units range from \$1,500 to \$1,650 per month, average rental rates for two-bedroom units range from \$1,600 to \$2,275 per month, and average rental rates for three-bedroom units range from \$1,700 to \$2,250 per month. In Corona, average rental rates for one-bedroom units range from \$1,100 to \$1,425 per month, average rental rates for two-bedroom units range from \$1,600 to \$1,850 per month, and average rental rates for three-bedroom units range from \$1,800 to \$2,250 per month. Average rental rates for one-bedroom units in Flushing range from \$1,200 to \$1,800 per month, average rental rates for two-bedroom units range from \$1,450 to \$2,200 per month, and average rental rates for three-bedroom units range from \$1,500 to \$4,900 per month. These rentals rates are higher than the ACS median contract rent, which includes rent-regulated and rent-controlled apartments.²

ESTIMATE OF NON-REGULATED HOUSING

Rental rates in New York City are controlled through several mechanisms. These include rent regulation (either rent control or rent stabilization), direct public subsidies to landlords, and public ownership. In New York City, the rent control program applies to apartments in residential buildings that contain three or more units and were constructed before February 1947. Only apartments in which the tenant has lived continuously since before July 1, 1971 may fall under rent control. When a rent-control apartment becomes vacant, it either becomes rent stabilized or, if it is in a building with fewer than six units, it is removed from regulation. Rent stabilization limits the annual rate at which owners may increase rents. In New York City, rent

¹ Average listing for Sky View Parc was obtained from Streeteasy.com on December 28, 2012.

² Average rental rates were obtained from searches for apartment listings on Streeteasy.com and Elliman.com conducted on November 15, 2012.

Willeys Point Development

stabilization generally applies to apartments in buildings containing six or more units that were built between February 1, 1947 and January 1, 1974. An apartment is no longer protected by rent stabilization if it becomes vacant and could be offered at a legal regulated rent of \$2,000 or more, or if the legal rent is \$2,000 and the apartment is occupied by tenants whose total annual household income exceeded \$175,000 for each of the past two years.¹ Regulated and non-regulated housing in the study area is discussed below.

Other types of rent-regulated housing include Section 8 housing, public housing, Mitchell-Lama developments, and other HPD-owned housing. The ¾-mile study area does not contain any Mitchell-Lama housing, but does contain three public housing developments: the Bland Houses, Latimer Gardens, and Leavitt Street-34th Avenue, all discussed below.

Study Area

This section describes existing conditions in the study area in terms of the status (rent-regulated or non-regulated) of housing stock in the ¾-mile study area. In accordance with the *CEQR Technical Manual*, the number of unregulated units in the study area was estimated based on Census data and data obtained from the New York City Department of Finance's RPAD database. **Table 3-23** shows the calculations and the estimated count of unregulated units in the study area. As shown in the table, the estimate was based on the number of units in the study area that met the following criteria and were therefore assumed to be unprotected from rent increases:

1. The units are in buildings that are privately owned (i.e., not public housing units);
2. The units are in buildings not old enough to be subject to rent control or rent stabilization; and/or
3. The units are in buildings too small to be subject to rent control or rent stabilization.

Based on these criteria, the ¾-mile study area contains approximately 12,291 renter-occupied units that are currently unprotected from rent increases. These unprotected rental units represent approximately 65 percent of the total housing stock in the study area; the remaining 35 percent of the study area housing stock is rent-regulated or owner-occupied.

Table 3-23

Estimated Unprotected Rental Housing Units in the ¾-Mile Study Area

Row	Units Identified	Components	Total for Study Area	Notes
1	Base of Unprotected Units:	Number of units in buildings with 1-5 units	11,183	Derived from RPAD
2	Units in Small Buildings (1-5 Units)	Estimate of rental units in 1 - 5 unit buildings	7,935	(Row 1) X (Renter occupancy rate for the study area)
3	Additional Unprotected Units: Buildings Built After 1974	Total units (renter and owner occupied) in buildings built after 1974 with more than 5 units	6,138	Derived from RPAD
4		Estimate of rental units in buildings with more than 5 units, built after 1974	4,355	(Row 3) X (Renter occupancy rate for the study area)
5	All Unprotected Rental Units	Estimate of renter-occupied units that are unprotected	12,291	(Row 2) + (Row 4)

¹ Rent regulations obtained from the New York State Division of Housing and Community Renewal, Office of Rent Administration and the New York City Rent Guidelines Board.

POPULATION POTENTIALLY AT RISK OF INDIRECT DISPLACEMENT

Populations potentially at-risk of indirect residential displacement are defined as people living in privately held units that are not protected by rent regulations, whose incomes or poverty status indicates that they could not afford to pay substantial rent increases. This section estimates the population potentially at-risk of indirect residential displacement in the $\frac{3}{4}$ -mile study area.

In order to identify populations in the study area potentially at risk of indirect displacement, the population of low income renters in the study area was estimated, and then adjusted according to the estimated proportion of rental units that were unprotected. The following steps were used to identify population at risk, and the calculations are shown in **Table 3-23**:

1. Estimate the low income population in renter-occupied housing units in the study area.

The low income population in renter-occupied housing units for the study area was estimated using Public Use Microdata Sample (PUMS) data, which is available for specific geographies called Public Use Microdata Areas (PUMAs). PUMS data on household income for renter-occupied housing units by household size was collected for the PUMA that most closely approximates the study area.¹ The share of low income renter households in the PUMA was calculated (45.7 percent).² This proportion was applied to the total renter population in the study area in order to estimate the low income renter population in the study area (28,431 residents).

2. Estimate the low income population living in unprotected rental units in the study area.

The low income population living in unprotected rental units—the population potentially vulnerable to indirect residential displacement—was estimated by multiplying the proportion of rental units in the study area that are unprotected (64.6 percent) by the low income renter population calculated above.

As shown in **Table 3-24**, there are an estimated 18,357 low income residents living in unprotected rental units in the study area. This potentially vulnerable population represents 21.7 percent of residents in the study area.

Between the Draft and Final SEIS, the U.S. Census Bureau, in consultation with DCP HEIP, currently is developing worked to develop additional data for use in CEQR analyses of indirect residential displacement. These data may were intended to allow the analysis to further refine the location and numbers of study area residents who may be potentially vulnerable to displacement. If this data becomes available and if deemed appropriate by the lead agency, the analysis of indirect residential displacement may be updated to incorporate this additional data between Draft and Final SEIS. DCP received and reviewed the data, finding that they could not be utilized because they were based on too limited a sample size to provide statistically accurate estimates. Therefore, the data are not being used for CEQR analyses and were not used in this SEIS.

¹ PUMS data for PUMA 4107 was used for this analysis. PUMA 4107 approximates Queens Community District 4, though the two are not coterminous. PUMA 4107 includes Flushing Meadows Corona Park, which forms its southern boundary, and is bounded by the Van Wyck Expressway and 126th Street to the east. Between the Long Island Expressway to the south and 45th Avenue and Roosevelt Avenue to the north, PUMA 4107 extends west roughly to 74th Street.

² Low income households are defined as those that that meet the HUD-defined low (80 percent) income limits, by household size, for Queens County for FY2012.

Table 3-24

Estimated Population Potentially Vulnerable to Indirect Residential Displacement in the ¾-Mile Study Area

Row	Population Identified	Components	Total for Study Area	Notes
1	Low income population in renter-occupied housing units	Total population in renter-occupied housing units in study area	62,151	ACS 2007-2011 5-Year Estimates
2		Proportion of low income renter population in PUMA	45.7%	PUMA 4107 – Queens Community District 4, ACS 2011 5-Year Estimates, provided by DCP
3		Study Area low income renters	28,431	(Row 1) X (Row 2)
4	Population potentially at-risk of indirect residential displacement	Total unprotected units	12,291	From Table 3-23 , above
5		Total rental units in the study area	19,035	ACS 2007-2011 5-Year Estimates

THE FUTURE WITHOUT THE PROPOSED PROJECT

Since potential impacts of the proposed project are assessed in relation to the future without the proposed project, this section considers trends affecting rents and potential displacement that may occur in the future, absent the proposed project. Absent the proposed project, it is anticipated that by the 2018, 2028, and 2032 Build years, the project site will continue to be occupied by existing uses. However, other development projects planned in the study area are expected to add 3,428 housing units by 2032.

In the future without the proposed project, Corona will gain an estimated 366 residential units by 2032. Greater Flushing will gain an estimated 3,062 residential units by 2032, including several large developments: the RKO Keith Theater development will add 357 units; the River Park Place development will add 475 units; Phase II of the Sky View Parc will add 600 residential units; and Flushing Commons will add 620 residential units. In addition, the Elmhurst East Rezoning is expected to add 378 residential units to Greater Flushing. College Point is not anticipated to gain any residential units.

As shown in **Table 3-25**, the dwelling units planned for the study area in the future without the proposed project would increase the study area population by an estimated 10,638 residents, or 11.7 percent.

Table 3-25
Population and Housing Growth
2032 Future Without the Proposed Project

	Housing Units				Population			
	Existing Conditions	Additional by 2032	Total in 2032	Percent Change	Existing Conditions	Additional by 2032	Total in 2032	Percent Change
Study Area	31,269	3,428	34,697	11.0%	91,156	9,667	100,823	10.6%
College Point	475	0	475	0.0%	1,355	0	1,355	0.0%
Corona	12,170	366	12,536	3.0%	46,175	1,032	47,207	2.2%
Greater Flushing	18,624	3,062	21,686	16.4%	43,626	8,635	52,261	19.8%
Note: 1. Population estimates for planned projects in the No Action and With Action conditions assume an average household size of 2.82 persons, the average household size for Queens.								

These planned developments will continue the trend of increased residential development that has already occurred in most parts of the study area. In keeping with this trend, residential development will be concentrated in Flushing and in Corona, along Northern Boulevard. While it is not possible to know the socioeconomic characteristics of the estimated 9,667 residents who will be introduced to the study area by 2032 in the future without the proposed project, based on the fact that these projects will be market rate units and the trends in market rate rents and sales in the study area, it is likely that the new population would have incomes that are substantially higher than the current average for the study area.

PROBABLE IMPACTS OF THE PROPOSED PROJECT

This section considers the effects of the proposed project along with conditions expected in the future without the proposed project in 2032, in order to determine whether the identified vulnerable population would be at risk of displacement as a result of the proposed project. According to the *CEQR Technical Manual*, the assessment of the effects of the proposed project should consider how the real estate market conditions in the study area would change as a result of the proposed project, including whether land use or real estate market conditions would reduce the likelihood that a vulnerable population would be at risk of indirect displacement.

The proposed project would result in the development of an additional 5,850 residential units in the study area, increasing the housing stock to 40,547 residential units by 2032 and representing a 16.9 percent increase over the No Action condition. Based on the average household size for Queens (2.82 persons per household), the proposed project would add up to 16,497 residents to the study area. As shown in **Table 3-26**, when compared with the population expected to reside in the study area in the No Action condition, the proposed project would result in a 16.4 percent population increase in the $\frac{3}{4}$ -mile study area by 2032.

Table 3-26

Population and Housing Growth: 2032 Future With Proposed Project

	Housing Units				Population			
	2032 No Action Condition Total	With Action Additional	Total in 2032	Percent Change	2032 No Action Condition Total	With Action Additional	Total in 2032	Percent Change
3/4-Mile Study Area	34,697	5,850	40,547	16.9%	100,823	16,497	117,320	16.4%
Note: 1. The population added in the With Action condition includes 16,497 residents living in 5,850 residential units (assuming the average household size for Queens of 2.82 persons).								

Generally, if the detailed assessment identified a vulnerable population potentially subject to indirect displacement that exceeds five percent of the study area—or relevant sub-areas, if the vulnerable population is located within the subarea identified—it may substantially affect the socioeconomic character of the study area and a significant adverse impact may occur. However, if it is determined that a project would not cause drastic changes in the real estate market (because of its mixed-income composition or due to land use or real estate market conditions in an area), the project may not affect rents for some or all of the existing vulnerable units.

As described above, there is an estimated population of 18,357 residents in the study area who could be at risk of indirect residential displacement if their rents were to increase. There is the potential for upward pressure on rents in the study area irrespective of the proposed project, due to the existing trend toward market-rate development, particularly in the subareas of Corona and Flushing. The proposed project would contribute to this influence, but would not generate significant adverse indirect residential displacement impacts for the following reasons:

- The District is geographically separated from surrounding communities, limiting its potential to influence residential trends in those communities.** Residential markets within the study area are similar to the markets described in the 2008 FGEIS. The District is geographically separated from the communities of Greater Flushing, College Point, and Corona, limiting the potential effect that the proposed project could have on housing values in those areas since new development in Willets Point would be considered to be in a neighborhood separate from these surrounding neighborhoods, which have well-established markets and characters that are separate from the District. Corona is separated from the District by Grand Central Parkway. In the future with the proposed project (2032), the residential areas in Corona would be further separated from the residential development proposed for the District by the concentration of commercial development in Willets West. Greater Flushing is separated from the District by the Flushing River and the Van Wyck Expressway. The residential areas of Flushing are further separated from the District by concentrated commercial activity in downtown Flushing. Pedestrian connectivity between the District and Greater Flushing is also limited, as Roosevelt Avenue provides the only pedestrian access to the District from the east. Therefore, even the residents living physically closest to the proposed residential uses would be located at a ½-mile walking distance from the District, reinforcing the geographic separation of the residential markets. The residential communities in College Point are separated from the District by large commercial and industrial centers, including College Point Corporate Park and shopping centers and commercial plazas along the Whitestone Expressway. These barriers limit the visual and physical connection between the District and surrounding areas, making it likely that the

District would be considered a distinct neighborhood and separate residential market in the future with the proposed project.

Furthermore, to the extent that residential displacement would occur in the future, it would be influenced by factors other than the proposed project. These geographically separated communities would experience upward rent pressure due to planned projects that are within their distinct residential markets. Large mixed use developments such as the RKO Keith Theater Development, River Park Place, Flushing Commons, and Phase II of Sky View Park in Flushing would provide pressure on the residential markets in Greater Flushing in the future with or without the proposed project. The Corona residential market would be influenced by development on a smaller scale, but would nonetheless experience upward rent pressure from planned residential developments more immediate than the proposed project.

Overall, the residential market characteristics described in the 2008 FGEIS remain in place; multiple geographic boundaries and intervening land uses would limit the potential influence of the proposed project on residential market conditions in the surrounding residential communities. At the same time, planned residential development in the distinct residential communities in Corona, Greater Flushing, and College Point, would have greater potential to influence residential market trends in these communities than the proposed project.

- **By adding new housing units, the proposed project could serve to relieve rather than increase market pressure in the study area.** By 2032, the proposed project would introduce 5,850 new residential units to the study area. By adding a substantial number of new housing units, the proposed project could relieve, rather than increase, market pressure in the study area. The substantial number of market-rate housing units recently completed or currently planned in the study area indicates that there is high demand for housing in the study area. It is likely that demand for housing in the study area will continue to increase in the future with or without the proposed project. Thus, the proposed project could absorb housing demand that might otherwise be expressed through increases in rents in the study area. This could reduce displacement pressures on the at-risk population in the study area.
- **The proposed project would introduce over 2,000 affordable housing units to the study area.** Although the population that would be introduced by the proposed project may include a larger proportion of households at higher incomes, the proposed project's affordable housing component would ensure that a substantial portion of the new population would have incomes that would more closely reflect existing incomes in the study area. Overall, some portion of the population introduced under the proposed project may have socioeconomic characteristics that are different from the existing study area population; however, this is not expected to lead to significant indirect residential displacement.

G. DETAILED ANALYSIS OF INDIRECT BUSINESS DISPLACEMENT DUE TO RETAIL MARKET SATURATION

The preliminary assessment presented in Section E, above, found that the proposed project would not have the potential to saturate the retail market within a 5-mile Primary Trade Area. Nevertheless, in response to public comments on the Draft Scope of Work and to maintain a scope of analysis consistent with that presented in the 2008 FGEIS on this issue, this section presents a detailed analysis of the potential for indirect business displacement due to retail market saturation.

This detailed analysis follows *CEQR Technical Manual* methodology (Chapter 5, Section 332.3) in considering whether the proposed project may result in an increase in vacancy in retail store fronts, affecting the viability of neighborhood shopping areas in the study area. While competitive pressures do not necessarily generate environmental concerns, they become an environmental concern when they have the potential to result in increased and prolonged vacancy leading to disinvestment. Such a change may affect the land use patterns and economic viability of the neighborhood. As noted in the *CEQR Technical Manual*, indirect displacement due to market saturation is rare in New York City, where population density, population growth, and purchasing power are often high enough to sustain increases in retail supply.

The study area for this analysis is the approximately 5-mile Primary Trade Area described in Step 2 of the preliminary assessment and illustrated in **Figure 3-2**. The Primary Trade Area encompasses numerous local retail concentrations whose sales are derived almost entirely from within the Primary Trade Area, as well as regional retail destinations whose sales are drawn from the Primary Trade Area and beyond. From within the mix of retail concentrations in the Primary Trade Area, the detailed analysis focuses on locations where the proposed project's retail would have the greatest potential to draw frequent, repeat visits from customers of existing retail concentrations, thereby potentially affecting the business environment of those areas. In addition, retail concentrations located in close proximity to the project site are profiled regardless of whether they contain overlapping store types, and examined for their potential to be adversely affected by competition with the proposed project.

Similar to the analysis in the 2008 FGEIS, the analysis focuses on grocery stores in the immediate vicinity of the proposed project, in particular, because grocery stores generally serve as anchors for retail concentrations, and the proposed project could introduce stores offering products that substantially overlap with typical grocery store offerings. In addition, the SEIS analysis examines the future viability of anchors in regional retail centers, including movie theaters and restaurants, because the Willets West component of the proposed project would constitute a major new shopping and entertainment center, adding destination retail space to the Primary Trade Area.

EXISTING CONDITIONS

CONSUMER PROFILE OF PRIMARY TRADE AREA

The 5-mile Primary Trade Area contains over 1.7 million residents living in approximately 609,000 households. In 2010, the Primary Trade Area's median disposable income was approximately \$42,000 per household. As detailed in Step 4 of the preliminary assessment, according to ESRI, households in the Primary Trade Area spent an estimated \$9.7 billion on retail goods in 2010 (see **Table 3-9**). Approximately 32 percent was spent on shoppers' goods, 43 percent on convenience goods, and 25 percent on eating and drinking establishments. On a per household basis, Primary Trade Area residents spent roughly \$5,118 annually on shoppers' goods including an estimated \$458 at department stores, an average of \$6,909 annually on convenience goods including \$4,570 at grocery stores, and \$3,988 on eating and drinking establishments.

PROFILE OF RETAIL CONCENTRATIONS WITHIN THE PRIMARY TRADE AREA

The Primary Trade Area, from which the majority of customers of the proposed project are expected to originate, includes numerous retail concentrations that play an important role in the

economic needs of neighborhood residents, but also in the larger regional context of shoppers and consumers in Queens. The following describes 10 major retail concentrations within the 5-Mile Trade Area that, due to their proximity to the project site and/or overlap in retail offering, have the potential to be adversely affected by competition with the proposed project. The location of each profiled retail concentration is shown in **Figure 3-3**. Characterizations of the retail concentrations are based on field visits conducted by AKRF in December 2012.

1. Northern Boulevard from 68th Street to 114th Street

This portion of Northern Boulevard is located to the west of the project site. Approximately 3.5 miles from the project site at its farthest points, between 68th Street and 78th Street, the commercial strip primarily contains large retailers, particularly car dealerships and car wash businesses. Between 78th Street and 90th Street, there is a larger concentration of local neighborhood retail businesses as well as large supermarkets (Super and Mi Tierra) and drug stores (CVS, Walgreens, and Rite Aid). This commercial strip is interrupted by several blocks of public housing abutting Northern Boulevard between 90th Street and Junction Boulevard. The remainder of the commercial strip closest to the project site, between Junction Boulevard and 114th Street, contains a concentration of industrial and commercial supply businesses, including sign making shops, auto body repair shops, and restaurant supply businesses. This section of the strip also contains smaller neighborhood retail businesses that serve the residential communities located immediately to the north and south, particularly the Hispanic community.

2. Northern Boulevard between Union Street and Utopia Parkway

This portion of Northern Boulevard east of the project site extends to the north of downtown Flushing. It contains a similar mix of businesses as the Northern Boulevard Area west of the Flushing River, with auto-related businesses interspersed with neighborhood retail businesses. Most of the small stores along this strip offer neighborhood services or convenience goods, including several supermarkets that cater to surrounding Asian population (HMart, GW Market, and Hanyang Mart). Many shops are in one-story buildings; however, the area also includes several small shopping plazas, including the Koreaville Plaza near 150th Street and the Galaxy Plaza near 159th Street. These plazas are similar to the shopping centers located in downtown Flushing and contain a mix of small local retail businesses and services (such as insurance offices, accountants' offices, and salons) serving the Asian community. As the residential density in the area decreases east of 167th Street and the neighborhood becomes more suburban in scale, the retail corridor becomes less concentrated, with more homes and fewer businesses abutting Northern Boulevard.

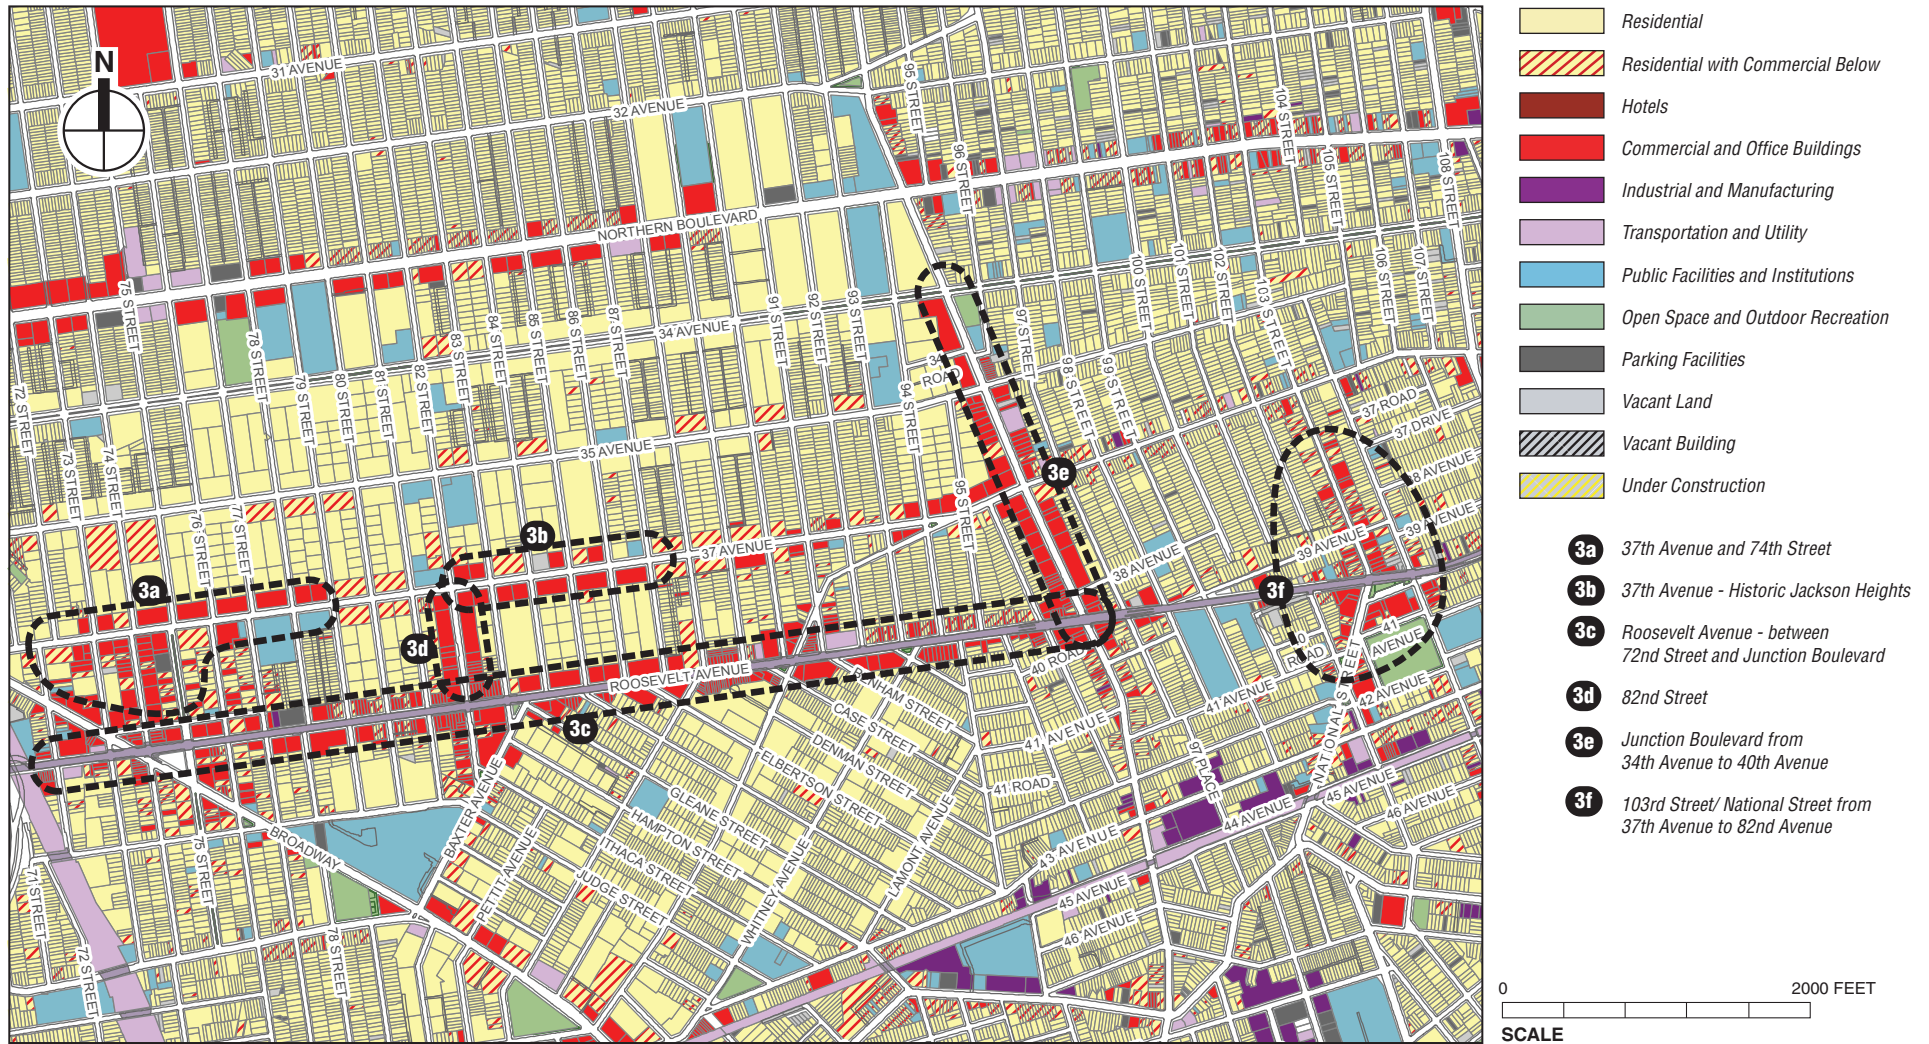

3. Roosevelt Avenue and 37th Avenue, Jackson Heights

West of the project site within Jackson Heights, 37th Avenue and Roosevelt Avenue are major retail concentrations that include the following retail strips (illustrated in **Figure 3-4**):

37th Avenue and 74th Street

37th Avenue contains a local retail section primarily serving the South Asian (Indian, Pakistani, and Bangladeshi) community between 78th Street and 86th Street, containing a large concentration of restaurants, supermarkets, and small grocery stores. This section includes a commercial strip extending south along 74th Street, containing a similar concentration of food-related businesses as well as several neighborhood retailers, such as jewelry stores. Eagle Plaza, a multi-story commercial facility located at the intersection of 74th Street and Roosevelt

Retail Clusters within the 5-Mile Radius Trade Area:
Roosevelt Avenue/ 37th Avenue/ Jackson Heights
Figure 3-4

Willets Point Development

Avenue, contains a mix of local retailers and services, including legal offices, serving the South Asian community.

37th Avenue—Historic Jackson Heights

The 37th Avenue commercial strip also contains a section serving a slightly more affluent community. This section is located in a more historic section of Jackson Heights, centered on the Mt. Sinai medical practice building between 82nd Street and 83rd Street. While this section similarly contains a concentration of neighborhood retailers, it contains a higher mix of clothing boutiques and local services.

Roosevelt Avenue—between 72nd Street and Junction Boulevard

Jackson Heights also contains a retail strip along Roosevelt Avenue between 72nd Street and Junction Boulevard. This strip primarily serves the Hispanic community in the area, and includes a large concentration of neighborhood retailers, including grocery stores, and local services. On several blocks, two-story retail building abut Roosevelt Avenue, with small shops or restaurants located on the first floor and local service businesses (including legal or medical offices) located on the second floor. This commercial strip also includes a larger retail facility located between Whitney Avenue and 94th Street, which contains a Staples office supply store.

82nd Street

Jackson Heights also contains an active destination shopping districts located along 82nd Street. The district contains a mix of local retail and value retail businesses that serve a slightly larger area, such as apparel and electronics stores. These districts also include several national chain retailers, such as Radio Shack and Gamestop.

Junction Boulevard from 34th Avenue to 40th Avenue

This neighborhood retail strip extends from 34th to 40th Avenues along Junction Boulevard. The strip contains a mixture of shoppers' and convenience goods stores, including clothing, shoe, and furniture stores, as well as pharmacies, restaurants, grocery stores, and 99 cent stores. The strip appears to be more heavily weighted toward shoppers' goods than convenience goods. Larger stores include VIM clothing store, Payless Shoe Source, Food Dimensions grocery store, and a Junction Food Bazaar grocery store at Junction Boulevard and 34th Avenue. Chain retailers have a stronger presence along this corridor—food stores and restaurants in particular—cater to a Hispanic population. Transit service to the corridor is good, with a No. 7 subway line express train stop located at Junction Boulevard and Roosevelt Avenue.

103rd Street/National Street from 37th Avenue to 42nd Avenue

The National Street/103rd Street retail concentration is a narrow retail corridor that runs from 37th Avenue to 42nd Avenue and is bisected by Roosevelt Avenue. Stores along this corridor offer mostly convenience goods, such as a 99 cent store, several delis, and a grocery store, as well as neighborhood services like a beauty salon and a barber shop. There are also several limited-service restaurants and shopper's goods stores. Several of the stores appear oriented toward serving the local shopping needs of the surrounding Hispanic community. Pedestrian traffic is highest at 103rd Street and Roosevelt Avenue, where the 103rd Street-Corona Plaza No. 7 subway station is located.

4. Northern Boulevard, Woodside

The commercial strip along Northern Boulevard in Woodside, between 39th Street and 55th Street, is approximately 3.5 miles to the west of the project site. Similar to the commercial portion of Northern Boulevard to the east of 68th Street, this commercial strip contains a concentration of car dealerships and other car-related businesses, such as gas stations and tire

stores. This area also contains a number of chain retailers, including Staples, Home Depot, Best Buy, Toys R Us, Sports Authority, Old Navy, and Marshalls, as well as chain eating and drinking businesses, such as Starbucks Coffee, Boston Market, and Pizza Hut. Several of these businesses are collected in the Tower Square shopping plaza located on the corner of Woodside Avenue and Northern Boulevard.

5. Downtown Flushing

Downtown Flushing is situated to the east of the project site, separated by the Flushing River, and its retail district is centered at the corner of Main Street and Roosevelt Avenue. Downtown Flushing is a full-scale Central Business District (CBD) with a combination of office and retail uses. Flushing has a vibrant retail district with a broad range of store sizes and types, and an active business community supported by the Downtown Flushing Transit Hub Business Improvement District. Downtown Flushing can be reached by the No.7 train subway, which has a station at the corner of Main Street and Roosevelt Avenue, or by any of the approximately two dozen bus lines that converge at the downtown area.

Several large national chain stores, including Macy's and Old Navy, are located at the corner of Main Street and Roosevelt Avenue. Sky View Center, which opened in 2010 as part of the Sky View Parc development on College Point Boulevard near the CBD, is a regional shopping mall that also contains several national chain stores, such as Target, Bed Bath and Beyond, and Best Buy. However, the downtown Flushing CBD primarily consists of a variety of smaller convenience and shoppers' goods stores, a large proportion of which cater to the Asian residential population living in Flushing. Many of these smaller stores are located within shopping plazas or malls scattered throughout the CBD, such as the Flushing Mall, New World Mall, and Queens Crossing.

In addition to small conveniences and shoppers' good stores, downtown Flushing contains a number of large food stores. The food stores located along Main Street close to the denser shopping district, including Good Fortune Supermarket and Chung Fat Supermarket, are neighborhood stores that serve the local Asian community and are easily accessed on foot. Assi Plaza, located to the west of the CBD along College Point Boulevard, and Sky Food, located within Sky View Center, are larger food markets that also cater to the Asian community and offer a wider array of products. Assi Plaza is most easily accessed by car, and therefore likely attracts visitors from a wider part of the Flushing neighborhood. A Western Beef supermarket, also located on College Point Boulevard, provides wholesale-style groceries, including bulk meat and produce sales, and similarly attracts visitors travelling to the area by car.

Main Street from Sanford Avenue to Dahlia Avenue

Main Street continues to function as a retail corridor south of Downtown Flushing from Sanford Avenue to Dahlia Avenue. This stretch of Main Street has fewer shopper's goods stores and more neighborhood services and convenience goods. Pedestrian traffic is generally less than within downtown Flushing, but still high overall. This stretch has several small grocery stores and delis, including grocery stores focusing on Asian-Indian groceries and Halal foods.

6. College Point Shopping Center

The College Point Shopping Center is located on 20th Avenue between 132nd Street and the Van Wyck Expressway in College Point. The center opened in 1998 and today includes a variety of destination retail stores, including Old Navy, Modell's Sporting Goods, Babies R Us, BJ's

Wholesale Club, TJ Maxx, Target, P.C. Richards and Sons, Petco Animal Supplies, and Staples, along with chain eating and drinking establishments such as McDonalds and Starbucks.

7. Queens Boulevard, Elmhurst

Queens Boulevard contains three large malls between 55th Avenue and 64th Avenue, approximately 2 miles southwest of the project site. These malls—the Rego Center, Queens Center and Queens Place—contain predominantly national retail chains and serve shoppers travelling from outside of the neighborhood on public transit (via the nearby Woodhaven Boulevard station on the M and R subway lines) or by car (via Queens Boulevard or the Long Island Expressway). The businesses in the area are typical for a destination shopping district: large department store anchors (Kohl's, Sears, Target, Macy's, and JC Penney), big-box retailers (Best Buy, Costco, Bed Bath & Beyond), large clothing stores (Century 21, TJ Maxx, Old Navy, Marshalls), and other national chain retailers such as Toys R Us and the Disney Store. The facilities also contain a mix of smaller chain retail stores, particularly apparel stores such as Banana Republic, and food court facilities with chain eating and drinking businesses such as KFC and Panera Bread.

8. Woodhaven Boulevard and Atlas Park, Glendale

Woodhaven Boulevard

Several large retail businesses are located in a shopping plaza along Woodhaven Boulevard between Metropolitan Avenue and the rail overpass. They include national retail chains such as Home Depot, and Staples, as well as a Trader Joe's grocery store. Access to the plaza is limited due to the adjacent wide streets and the railroad lines, and can best be reached by car on Metropolitan Avenue; it is particularly isolated from the residential neighborhoods located immediately to the east and west.

Atlas Park

The Shops at Atlas Park, located several blocks to the west of the Woodhaven Boulevard shopping center, is a plaza-style shopping center that contains a number of small retailers. The shops are situated around a circular park and walking area, and are primarily upscale clothing and accessory boutiques. The retail center changed ownership in 2011, and has struggled to attract and retain tenants in recent years, in part due to its relative isolation (shoppers arriving by car can enter garages attached to the center off of Cooper Avenue and 80th Street, but access on foot is limited) and the lack of an anchor retailer such as a department store.

9. Downtown Jamaica

Downtown Jamaica is a traditional CBD area, situated roughly 4 miles to the southeast of the project site. Retail activity focuses on Jamaica Avenue between 146th Street and 172nd Street, with additional concentrations of storefronts located on 165th Street, New York Boulevard, Sutphin Boulevard, and 164th Street. The area is easily accessible by public transportation, with subway stations serving the E, J, Z, and F trains all within walking distance of the CBD, an LIRR train stop located at Sutphin Boulevard and Archer Avenue, and over 20 different bus lines running through the downtown area.

The CBD includes a variety of both shoppers' and convenience goods stores, and appears to have a particularly high concentration of stores offering clothing, shoes, and clothing accessories. Citywide or national chain stores of this type located in Jamaica include VIM, Dr. Jays, Strawberry's, Payless Shoe Source, Gap, and Old Navy. However, the area does not contain a traditional retail anchor, such as a large department store. One block of 165th Street,

between Jamaica and 89th Avenues, serves as a pedestrian mall. Retail activity in downtown Jamaica is very active.

10. Fresh Meadows Shopping Center

The Fresh Meadows Shopping Center is located between 188th Street and 194th Street adjacent to the Long Island Expressway, approximately 3 miles southeast of the project site. The shopping center is connected to the Fresh Meadows housing development, and contains several local shops, services and entertainment options, including a cinema, that serve the development's residents; outside of the shopping center, local retail options in the area are limited to a corridor on Union Turnpike. The shopping center also contains an anchor retailer, a Kohl's department store, as well as smaller chain clothing retailers, such as Dress Barn. These retailers likely attract shoppers from a wide area arriving by car.

THE FUTURE WITHOUT THE PROPOSED PROJECT

The two primary factors that would affect retail conditions in the 5-mile Primary Trade Area in the future without the proposed project include: 1) population growth, which could increase expenditure potential and generate additional demand for retail goods; and 2) new retail projects, which would expand the retail inventory.

In terms of population growth, as described in Step 6 of the preliminary capture rate analysis, the portion of the Primary Trade Area within an approximately 1-mile radius of the project site is expected to add 2,706 new households by 2018. Outside of this 1-mile area, there are no significant residential projects known to be planned or under construction within the Primary Trade Area. With the 2,706 new households in place, the Primary Trade Area will contain an estimated 611,439 households. As shown in **Table 3-9**, Primary Trade Area households currently spend approximately \$16,016 per year on the three retail categories highlighted in this analysis. If the additional households continue to spend the same amount per year, the new households would increase the retail demand by \$43.34 million. These households would spend approximately \$13.85 million on shoppers' goods (including \$1.24 million at department stores), \$18.70 million on convenience goods (including \$12.37 million at grocery stores), and \$10.79 million at eating and drinking establishments. Thus, the total household expenditure potential for retail goods—including the additional households anticipated in the No Action condition—will be approximately \$9.8 billion in the future without the proposed project by 2032.

In terms of retail development, research on projects either planned or currently under construction within the Primary Trade Area, conducted in connection with Step 6 of the preliminary assessment, identified several projects with large retail components. For the purposes of this analysis, planned projects with more than 50,000 gsf of retail space have been identified as having a high potential to contain a destination retail facility, such as a department store. These larger retail facilities are the most likely to compete directly with the destination retail of the proposed project. This excludes neighborhood-wide projects, such as rezoning, that may introduce a large amount of retail over an extended geographic area, but does not necessarily introduce large destination retail facilities on individual sites. **Table 3-27** shows the applicable destination retail projects.

Table 3-27
Planned Destination Retail Projects
Future Without the Proposed Project

Fig.2-4 Site No.	Location/Address	Retail gsf	Build Year
19	Block bounded by Astoria Boulevard, Northern Boulevard, and 112th Place	73,329	2018
26	37-19 College Point Boulevard	56,595	2018
14	Flushing Commons (Municipal Parking Lot 1) and Macedonia Plaza: block bounded by 138th Street, 37th Avenue, 39th Avenue, and Union Street	300,000	2018/2028
44	Caldor Site, 136-20 Roosevelt Avenue	155,000	2016
Notes: Listed projects are limited to large single-site developments located within approximately 1 mile of the proposed project			
Sources: AKRF, Inc.			

The full 5-Mile Primary Trade Area extends to include a majority of Queens and a portion of Brooklyn. Given the scale of this geography and the long time horizon associated with the 2032 Build year, it would be speculative to project the amount of residential and retail development that is likely to occur by 2032 for the Primary Trade Area. As stated in the *CEQR Technical Manual*, New York City's commercial streets are dynamic and are continually affected by changes in consumer spending, shopping trends, demographics, and population growth. Overall, in the future without the proposed project by 2032, it is expected that the retail landscape in the 5-mile Primary Trade Area will continue to evolve consistent with current trends, with natural turnover and growth in retail uses and growing household retail demand.

PROBABLE IMPACTS OF THE PROPOSED PROJECT

As described in the *CEQR Technical Manual*, there may be potential for a significant adverse impact on retail businesses if a project would decrease shopper traffic on commercial streets such that retail vacancies rise and retail businesses in the study area are no longer economically viable. This should be considered likely if the following conditions are met:

- The proposed anchor stores have potential to affect the ability of existing stores selling similar categories of goods to capture the sales volume necessary to remain in business;
- These existing stores draw a substantial share of shopper traffic to the neighborhood commercial strips on which they are located, or the street contains a concentration of businesses that sell the relevant categories of retail goods; and
- Limited demand for retail tenants is expected.

As noted above, the analysis focuses on shopping center anchors and local food stores because grocery stores generally serve as anchors for retail concentrations, and the proposed project could introduce stores offering products that substantially overlap with the retail offerings at grocery stores and shopping center anchors.

POTENTIAL IMPACTS ON LOCAL FOOD STORES

The Northern Boulevard, Roosevelt Avenue, and Downtown Flushing retail corridors contain a wide variety of food and beverage stores, including several large supermarkets and smaller

independent stores such as delis and grocery stores, meat and fish markets, fruit and vegetable markets, and retail bakeries. Grocery stores in these retail clusters include supermarket chains, such as Trade Fair and C-Town. In many cases, the independent stores serve the local ethnic community, particularly the Hispanic and South Asian communities in Jackson Heights and the Asian community in Flushing. Several of the larger supermarkets, such as Sky Foods, Mi Tierra and HMart serve these communities as well. In total, there are approximately 27 supermarkets or grocery stores in these three local retail concentrations that could compete with the proposed project's food stores due to their close proximity and the potential for overlapping consumer base.

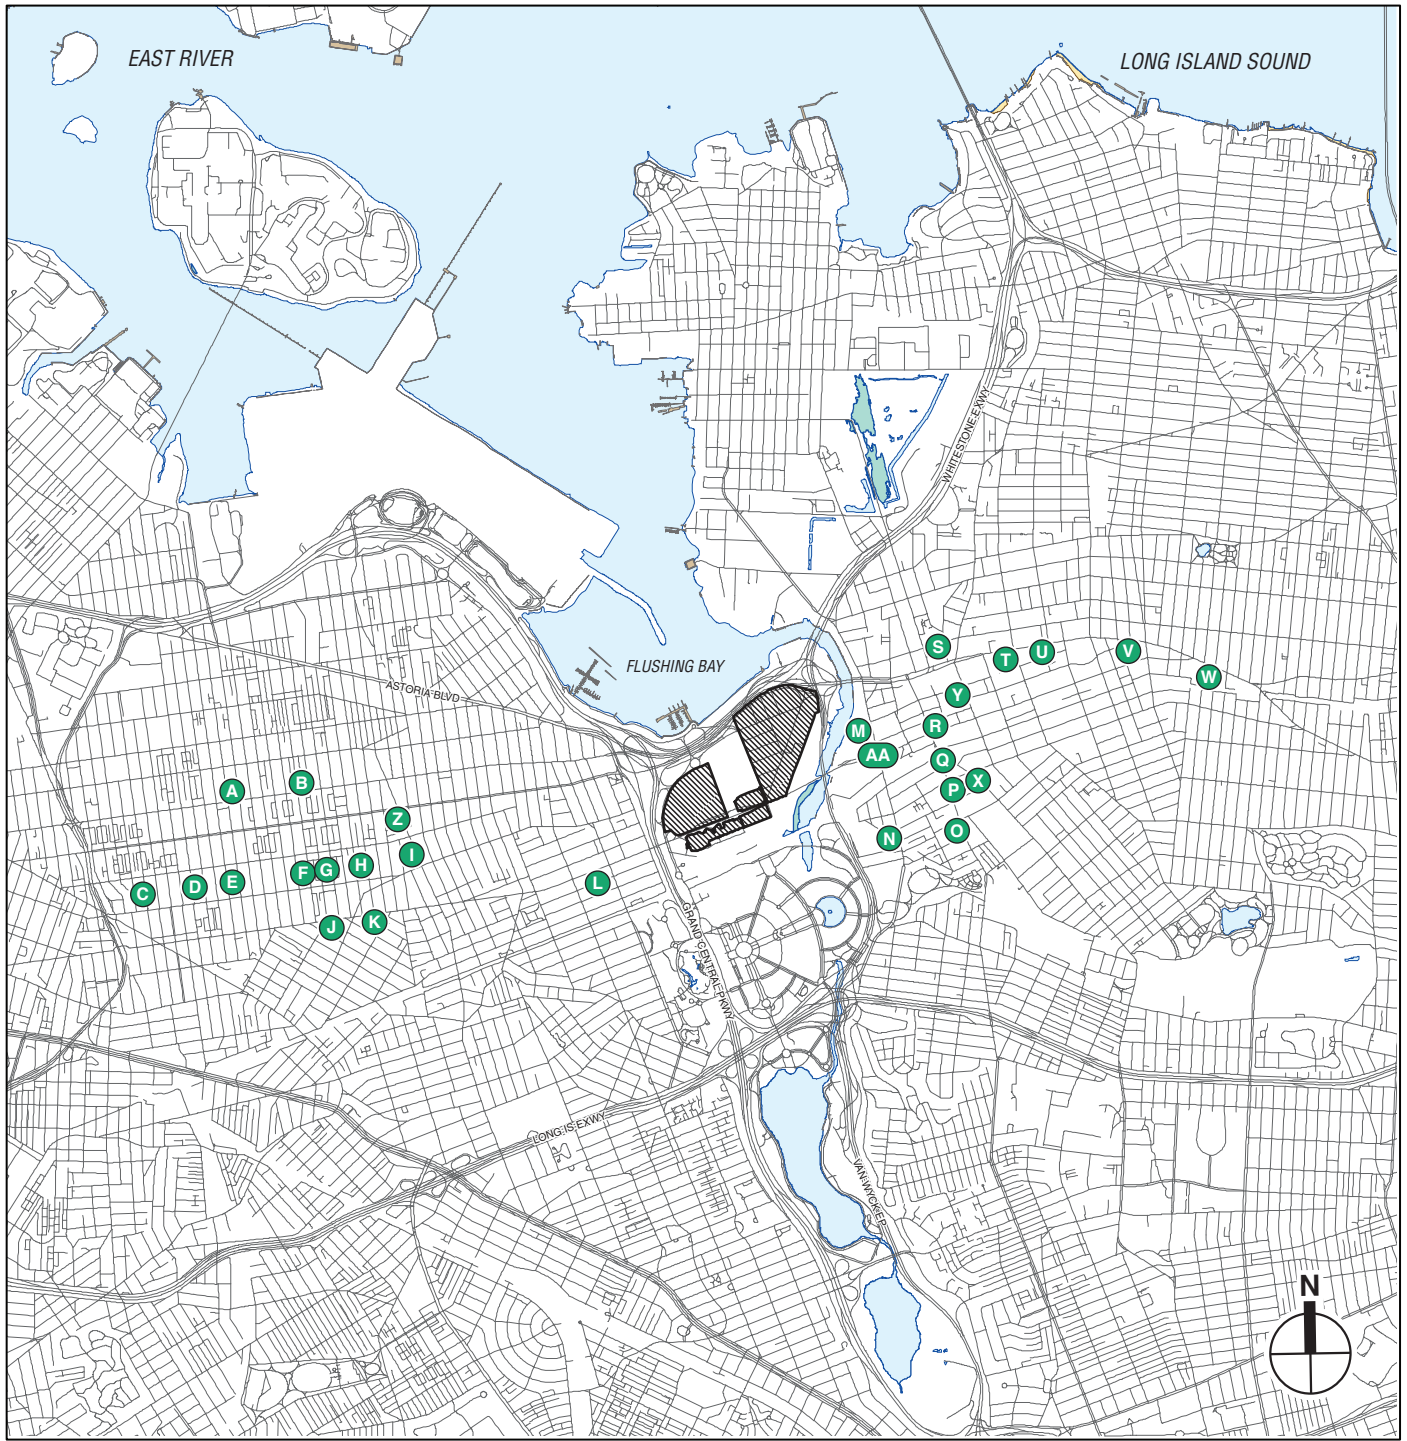

The names and locations of each supermarket or large grocery store are provided in **Table 3-28** and are mapped in **Figure 3-5**.

As described below, with the proposed project, the amount of competitive business displacement of grocery stores and local retail stores more generally would be minimal, is not anticipated to jeopardize the viability of any neighborhood retail strips, is not expected to diminish the level of services provided and, therefore, is not anticipated to result in significant adverse impacts due to retail market saturation.

Local stores would remain more convenient to many shoppers.

Local area residents would continue to make a majority of their shopping trips to stores closest to their homes and closest to public transportation. It is therefore unlikely that a large portion of consumer sales would be diverted from local stores to the proposed project's retail development. Many residents, especially those without access to a car, would continue to do the majority of their grocery shopping at the stores on the local retail corridors because they would remain more convenient and because transit service to the District would not be convenient for many residents of the neighborhoods adjacent to the project site. Although the District is served by the No. 7 subway line and the Q19, Q66, and Q48 buses, it is unlikely that residents would travel out of their way to access a transit route to the District, when many existing retail concentrations are nearby and are also well served by buses and subways. As discussed below, several of the local grocery stores also cater to a particular ethnic community living near the adjacent retail corridors. A supermarket or other food stores in the District is unlikely to attract a large number of shoppers who would normally shop at these specialty grocery stores.

In addition, the central locations of local grocery stores put them at an advantage over the District in some respects. Residents are likely to combine shopping trips for groceries with errands such as trips to the bank or dry cleaner, and may also shop for retail goods such as clothing, shoes, or books on the same trip. Many of the smaller grocery stores in the adjacent retail corridors are located along major commercial corridors that offer a variety of convenience goods, shopping goods, and neighborhood services, or in small retail clusters that include other basic convenience goods stores. Many residents, even those with access to a car, would continue to do the majority of their grocery shopping at these supermarkets because of the opportunity they provide for easily combining trips. It is therefore unlikely that a large portion of their sales would be diverted from local grocery stores to a supermarket or other food stores in the District.

Notes: Supermarkets greater than 10,000 sf are listed in bold . Sources: Store square footage based on the New York City Department of Finance's Real Property Assessment Data (RPAD) 2012 database, estimates from aerial photography, and AKRF field surveys conducted in December 2012.		

Small- to medium-sized, independently owned grocery stores, bodegas, and delis serve a retail function similar to specialty food stores, though they offer a wider variety of food items. In general, these smaller grocery stores tend to act as convenience stores, where customers make frequent trips and purchase fewer items that are in immediate demand, such as milk or bread, or housekeeping supplies such as light bulbs. While shoppers may sometimes purchase these types of goods at chain supermarkets, they typically do not make frequent trips for convenience goods to wholesale clubs or area supermarkets; instead, they are likely to continue to fill their more frequent convenience food and beverage needs at smaller, nearby grocery stores.

Many businesses in adjacent retail corridors cater to specific ethnic groups.

Many neighborhoods in Queens have a distinct character in terms of income levels and ethnic background of their residents. The local retail concentrations reflect the income and ethnic patterns of their local neighborhoods, with local retailers offering specialty goods and services familiar to a specific ethnic community and frequently doing business in a foreign language. For example, the corridors near 37th Avenue, and Roosevelt Avenue serve the nearby South Asian

and Hispanic communities in Jackson Heights, while the corridors near Main Street and Northern Boulevard serve the Asian community in Flushing. This is particularly true in the case of food stores in these areas, which specialty items, including imported goods, and are particularly suited to shoppers who do not speak English as their primary language (notably, several of the Asian supermarkets located in Flushing do not have websites translated into English). By focusing on specific, and in some cases, geographically small local market areas, these retail concentrations in Queens have maintained strong local support. And despite the fact that many of the local commercial strips draw from a small primary trade area (in some cases a two- or three-block radius), sales are high due to very high population densities. Furthermore, it is unlikely that the proposed retail would offer goods, services, or restaurants that would directly compete with the specialty goods, services, and ethnic restaurants offered by local retailers focusing on a specific ethnic community. Overall, many shopping areas would be likely to retain their customer base.

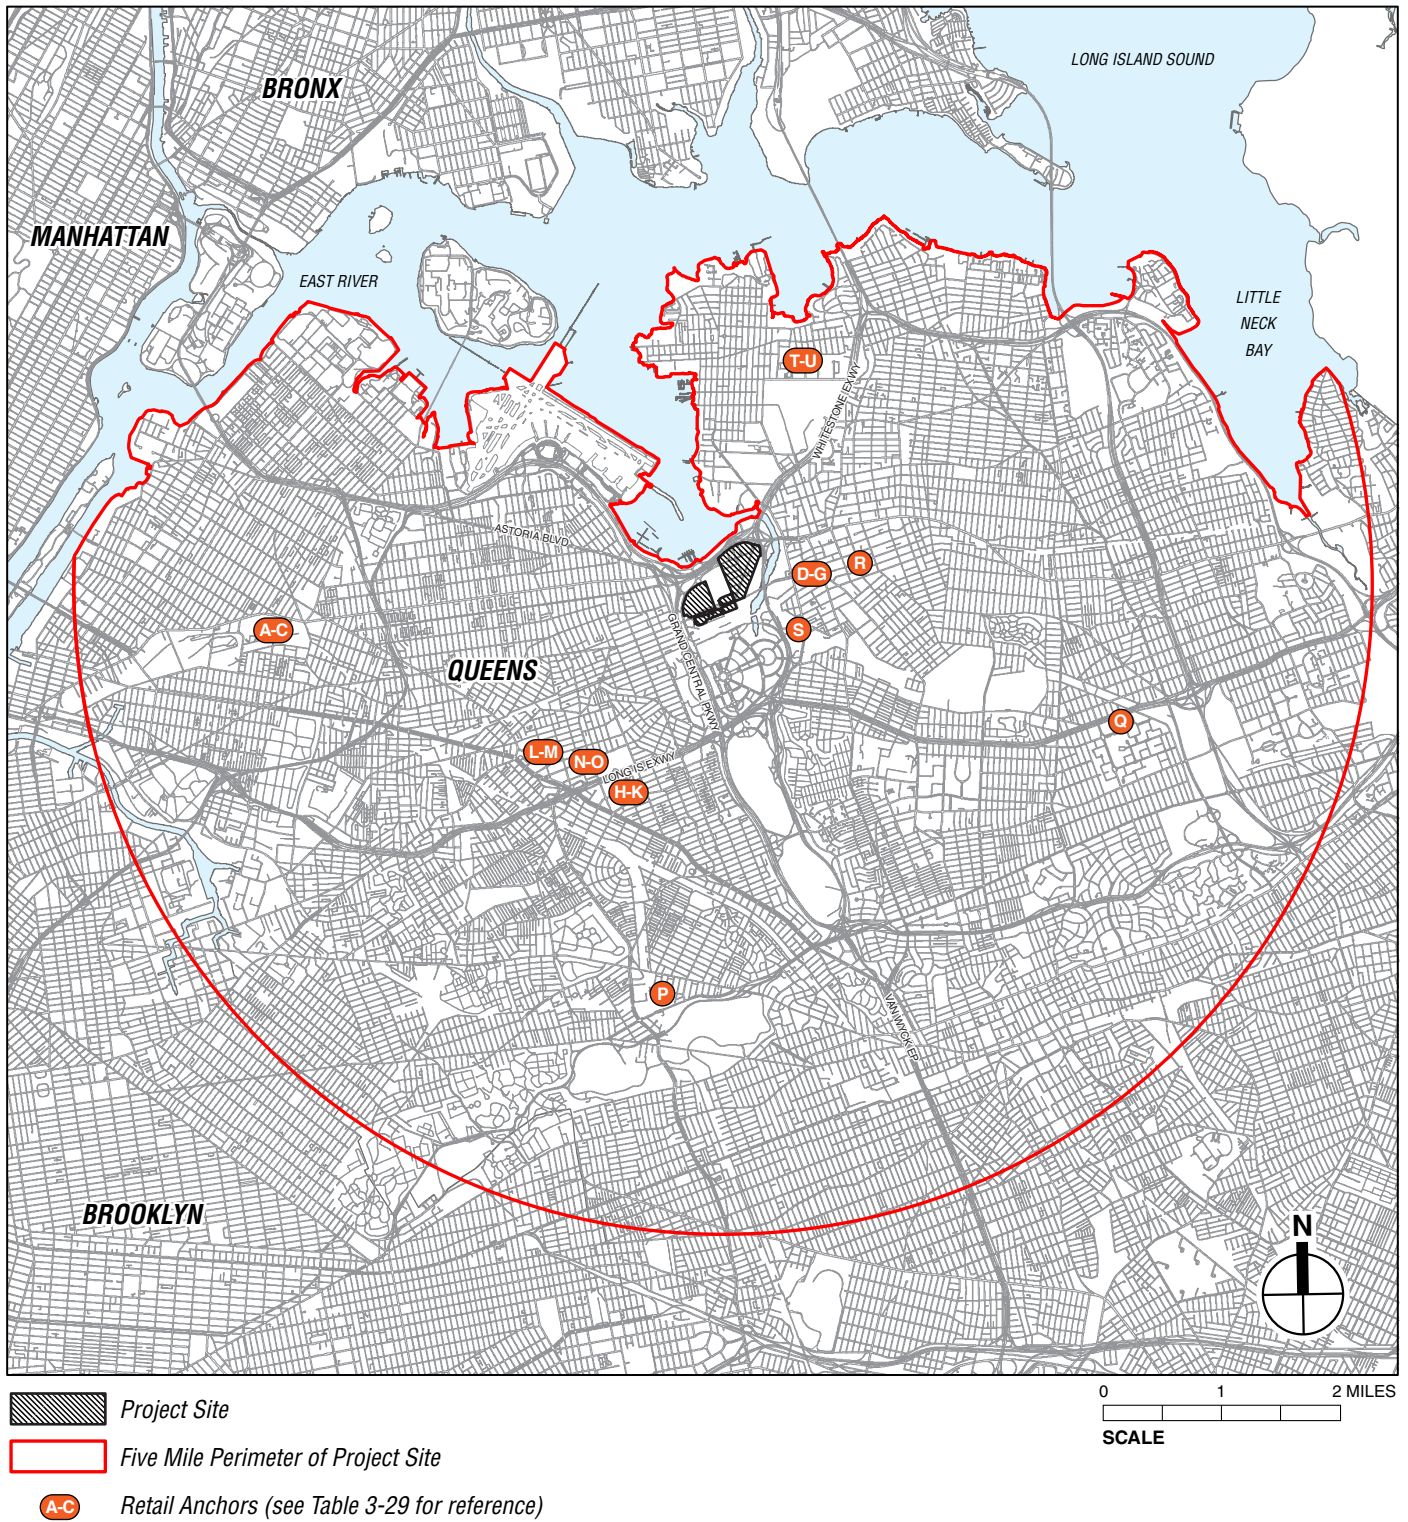

Many individual supermarkets in the adjacent retail corridors are not critical to the survival of local retail concentrations.

The potential for significant adverse impacts due to retail market saturation exists only if proposed stores have the potential to affect neighborhood character by affecting the viability of neighborhood shopping areas. The adjacent retail corridors contain approximately 27 supermarkets, several of which might serve as anchors of their respective retail concentrations. Smaller supermarkets, such as Met Food and C-Town, typically with less than 10,000 sf of space, primarily serve the convenience shopping needs of local residents, and so they would not directly compete with a supermarket at the project site. Even though one or more of these smaller grocery stores may be present on a local shopping street, they do not typically anchor the commercial mix and are not critical to the survival of surrounding stores, and so would not adversely alter neighborhood character even if they were to be negatively affected by competition.

POTENTIAL IMPACTS ON SHOPPING CENTER ANCHORS

Within the 5-mile Primary Trade Area, there are number of retail clusters that serve a customer base that extends beyond their immediate neighborhoods. In contrast to the local retail corridors, where supermarkets tend to function as anchors, these clusters are characterized by large-format anchor stores that sell shopping goods attracting customers from a broader region. The anchor stores of these retail clusters tend to draw traffic not only to the anchor store, but also to the smaller stores collocated with the anchor. Given this dynamic, if an anchor would be adversely impacted due to competition from the proposed project, the remaining stores in the cluster could also be affected.

Within the 5-mile Primary Trade Area there are shopping centers of varying size and character that contain anchor stores with trade areas and retail offerings that could overlap with the proposed project. **Table 3-29** identifies selected anchors of regional shopping centers within the Primary Trade Area, and their locations are illustrated in **Figure 3-6**.

For the reasons outlined below, with the proposed project, the competitive effects of the proposed project on anchor stores at shopping centers is expected to be minimal, is not anticipated to jeopardize the viability of any shopping centers, is not expected to diminish the level of services provided and, therefore, is not anticipated to result in significant adverse impacts due to retail market saturation.

The Primary Trade Area is not saturated by retail.

The presence of numerous retail anchors within close proximity of the project site shows that the Primary Trade Area is a robust market capable of supporting such stores in a variety of retail formats. So while there are a number of shopping centers within the Primary Trade Area that could potentially compete with the proposed project for customers, the expenditure analysis conducted for the preliminary assessment shows that Queens, and the 5-mile Primary Trade Area in particular, are currently under-retailed; Queens is capturing only 57 percent of the total retail expenditure potential of its residential population, while in the future without the proposed project, the Primary Trade Area will be capturing an estimated 66 percent of its residents' retail expenditure potential. Shopper's goods retailers will be capturing an estimated 67 percent of expenditures, while department stores, a subset of the shoppers goods category and in many instances an anchor of shopping centers, is predicted to capture only 41 percent of the Primary Trade Area residents' expenditure potential in the future without the proposed project (see **Table 3-13**).

Even with the proposed project, only approximately 77 percent of the study area's expenditure potential would be captured. The remaining 23 percent of potential expenditures (approximately

\$2.3 billion) would continue to not be captured by stores within the Primary Trade Area and would be spent in other parts of New York City and adjacent counties.

Although the proposed project could potentially increase competition among shopping centers and their anchors, the remaining significant leakage of expenditures into areas adjacent to study area is an indication that available expenditures are sufficient in size to absorb additional retail development and are not expected to cause substantial competitive effects.

Smaller retail centers will continue to draw from local consumer bases.

Many of the major retail centers within the Primary Trade Area—in particular, the retail clusters in Woodside, College Point, Woodhaven, and Fresh Meadows—have only one or two anchors and serve smaller trade areas, so that their respective trade areas would only partially overlap with that of the proposed project. Woodside, Woodhaven, and Fresh Meadows are also at the fringe of the Primary Trade Area and are expected to draw a significant amount of their customers from outside of the Primary Trade Area. The composition of retailers at these clusters also suggests that the draw is more local in character. Anchor Stores such as Home Depot, Sports Authority or Michaels, present at Woodside and Woodhaven, tend to have smaller trade areas and are less likely to compete with stores in the proposed project.

Larger retail centers will continue to draw from a regional customer base

Sky View Center together with Downtown Flushing, the shopping centers at Queens Center, and Downtown Jamaica offer a critical mass and a diverse range of retail products that attract customers from local neighborhoods but also from well beyond the local trade area. The shops at Skyview Center in Downtown Flushing cater mainly to the existing community. The center takes advantage of the foot traffic in Downtown Flushing and targets primarily Asian residents and visitors, who come from as far New Jersey and Long Island. Stores such as the Fay Da Bakery and Sky Food within the center offer products and services specifically tailored to Asian shoppers. Because of these segment specific offerings and the close proximity to Downtown Flushing, with its ethnic restaurants and food stores, many shoppers are expected to continue to frequent stores in the Skyview Center.

Although Downtown Jamaica has, similar to the project site, access to the subway system and the Long Island Rail Road, its character and distance from the proposed development are expected to minimize potential adverse effects from competition. Downtown Jamaica is characterized by many small retail stores, mainly along Jamaica Avenue, interspersed with a few large-format department and apparel stores. Downtown Jamaica's unique retail corridor environment, paired with good access to public transportation access and its abundance of value retailers, make downtown Jamaica a preferred location for urban shoppers primarily from east Brooklyn south Queens.

Overall, only the shopping centers at Queens Center, i.e., Queens Center Mall, Rego Park and Queens Place, offer a critical mass of products and services, similar location characteristics, and a larger number of anchors similar to the proposed project. Because of these attributes and their proximity to the proposed development, the shopping centers at Queens Center are expected to have a trade area that will overlap with that of retailers at the proposed development and therefore compete for customers. However, these retail centers will continue to be viable because they have an established customer base (Queens Center Mall is consistently ranked as

one of the country's highest grossing shopping centers in terms of sales per square foot)¹, they are easily accessible by transit (via the nearby Woodhaven Boulevard station on the M and R subway lines) or by car (via Queens Boulevard or the Long Island Expressway), and in the future with the proposed project there will still be unmet expenditure potential within the trade area for these types of retail offerings.

POTENTIAL IMPACTS ON MOVIE THEATERS

The proposed project would introduce an approximately 80,000-gsf movie theatre, which could increase competitive pressure on some existing movie theaters within the Primary Trade Area. Therefore, this analysis examines whether the proposed movie theater is likely to exert competitive pressure on existing theaters, and whether such pressure could lead to vacancies affecting the economic viability of the neighborhoods in which they area located.

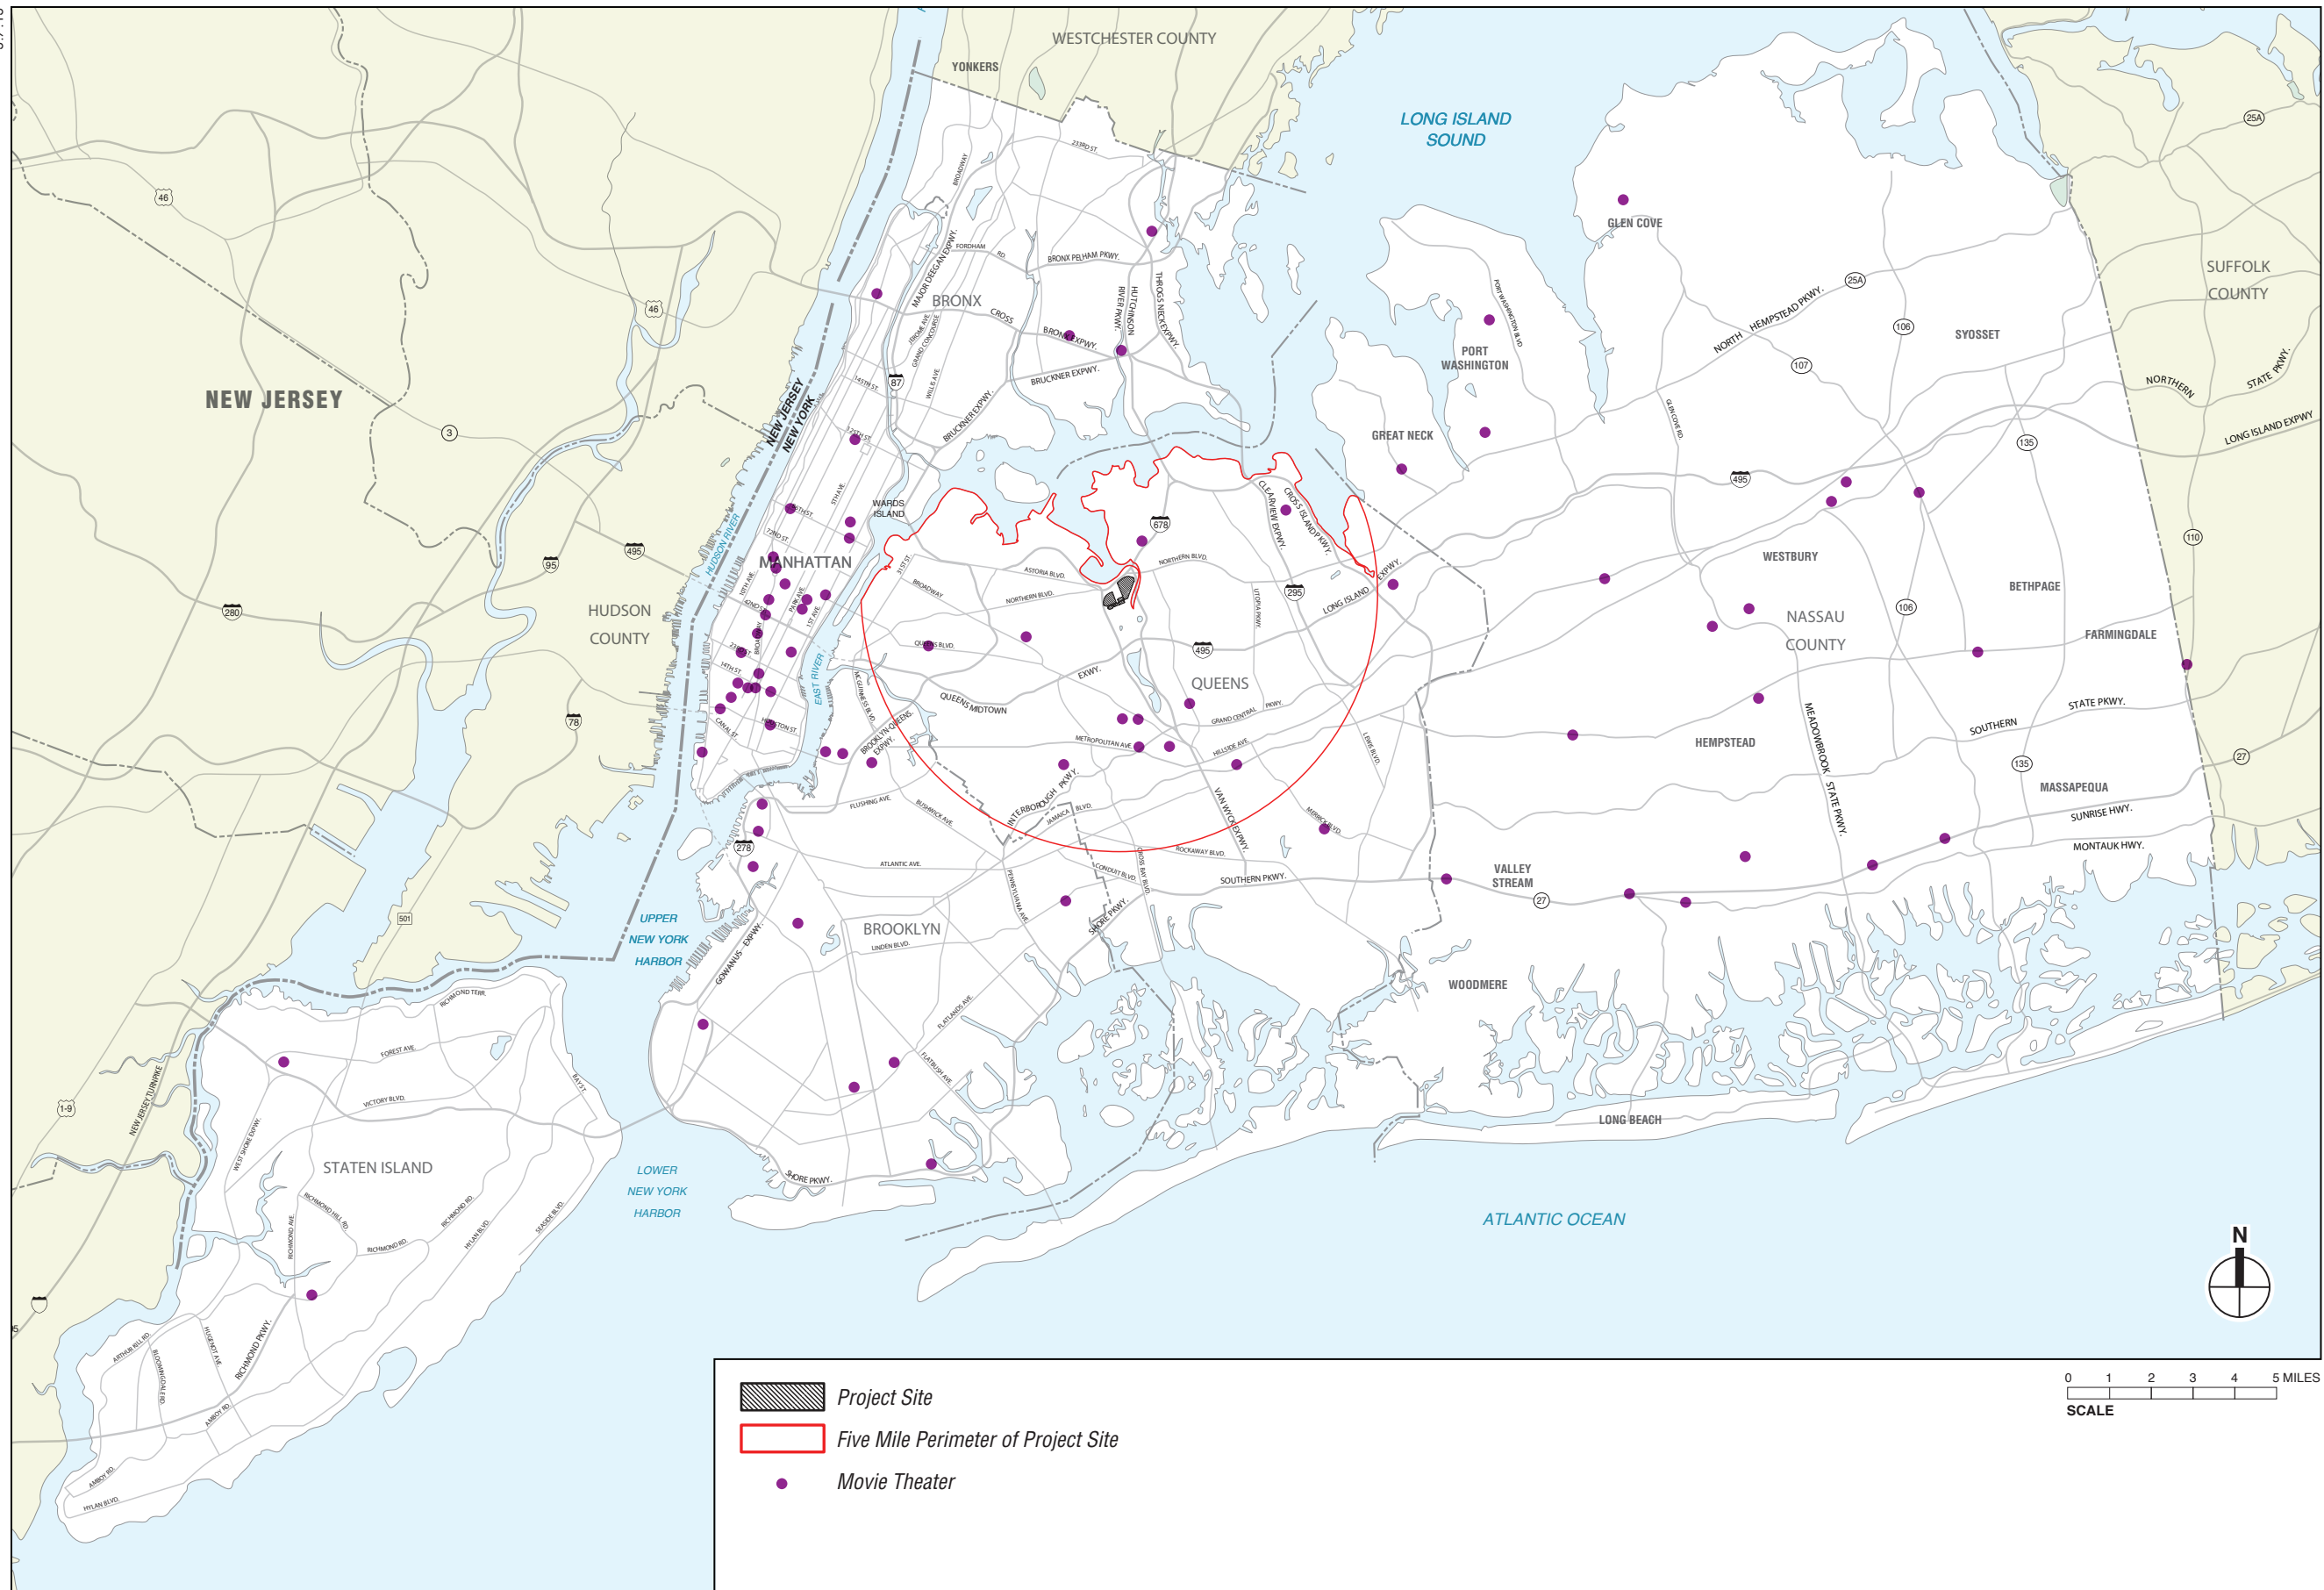

The proposed project theater would be a megaplex.² Megaplex theaters typically show new release movies with widespread appeal. For the proposed project theater, the area of potential overlap within the Primary Trade Area would be other large multiplex theaters—theaters that also focus on new release movies with mass appeal (see **Figure 3-7**). A substantial number of the movie theaters located in the Primary Trade Area are small-scale theaters that would not directly compete with the proposed movie theater. Many of the small-scale theaters in the Primary Trade Area, such as Fair Theatre in East Elmhurst (single-screen) and Jackson Heights Cinema in Jackson Heights (three-screen) show second-run, international, and/or independent films. These theaters tend to cater to a distinct audience and would not compete regularly with the proposed project's megaplex theater. While many small-scale movie theaters both within the Primary Trade Area and well beyond are struggling financially as their facilities age and new technologies and services make it easier for movie-watchers to access movies from home, these theaters would not be vulnerable to indirect business displacement due to competition from the proposed project's theater.

The multiplex theaters located in closest proximity to the proposed project site are in College Point (12-screen College Point Multiplex Cinema) and Forest Hills (nine-screen United Artists Midway Stadium 9 Theater). ESRI, the data provider utilized for the retail capture rate analysis presented earlier in this chapter, does not provide sales and household expenditure data for entertainment uses such as movie theaters. However, based on a review of business and search engine sites such as manta.com and google.com, the spatial distribution of movie theaters within the Primary Trade Area suggests that there is a potential market for a movie theater in the Willets Point area such that the planned movie theater would not have competitive effects on existing theaters. In fact, many areas appear to have greater concentrations of movie theaters than what exists in the Primary Trade Area. This is particularly evident when comparing the Primary Trade Area with Nassau County, which has about one quarter the population density of Queens but appears to have a comparable number of movie theaters.

While available information indicates that the existing market for multiplex movie theaters in the Primary Trade Area is unlikely to be saturated, if the proposed project were to have competitive

¹ In 2009 U.S. News reported that Queens Center was one of the 10 most profitable malls in the United States, with 98 percent of retail space occupied and sales of \$876 per square foot.

² A megaplex is a large multiplex theater, typically housing 16 or more movie theaters. (Merriam-Webster)

Movie Theaters in New York City
and Nassau County
Figure 3-7

effects on existing theaters, this would not be expected to lead to significant adverse neighborhood character impacts. The multiplex movie theaters that are located within the Primary Trade Area—those that would be most likely to compete with the proposed project’s megaplex—do not tend to anchor neighborhood retail concentrations. For example, College Point Multiplex Cinema on Ulmer Street is co-located with a Toys R Us and an Office Depot in a stand-alone building just off of Whitestone Boulevard. The three uses jointly anchor the building, which is surrounded by parking and disconnected from other retail businesses in College Point. In comparison, United Artists Midway Stadium 9 Theater in Forest Hills is located in a more densely retailed context, on Queens Boulevard in Forest Hills. However, this theater shares its block with a bank, a post office, and one restaurant. Banks and post offices rely more on concentrations of residential and office uses for customers rather than foot traffic generated by retail stores. Thus while the United Artists Midway Stadium 9 Theater is located along a more continuous retail corridor compared with the College Point Multiplex Cinema, it does not anchor a retail concentration. A third multiplex movie theater in the Primary Trade Area is the seven-screen AMC Fresh Meadows 7 on Horace Harding Expressway in Fresh Meadows. AMC Fresh Meadows is located in the Fresh Meadows Shopping Center, which includes a variety of stores and restaurants including Kohl’s, Filene’s Basement, Radio Shack, The Children’s Place, Applebee’s, and Starbucks. While the movie theater functions as a complementary use to the retail stores and restaurants, it does not anchor the shopping center.

Overall, the proposed project’s megaplex is not expected to lead to the indirect displacement of existing movie theaters in the Primary Trade Area. Many of the existing movie theaters differ from the proposed project theater in size and focus and therefore would not directly compete with the proposed megaplex. Existing multiplex theaters that may be more likely to compete with the proposed megaplex do not anchor retail concentrations and therefore even if limited displacement were to occur, this would not be expected to lead to prolonged vacancies that could affect neighborhood economic viability.

POTENTIAL IMPACTS ON RESTAURANTS

Individual restaurants do not tend to anchor neighborhood commercial concentrations. However, groups of restaurants can be important to the economic vitality of certain neighborhood retail areas. Since the proposed project would introduce up to 215,000 square feet of eating and drinking establishments, this analysis evaluates the potential for indirect displacement of eating and drinking establishments due to competition with the proposed project.

As indicated in the preliminary assessment of business displacement due to retail market saturation, the retail capture rate for eating and drinking establishments in the Primary Trade Area is estimated to be 56 percent in the future without the proposed project. Even with the addition of 215,000 square feet of proposed project eating and drinking space, the capture rate would be 65 percent in the future with the proposed project. This indicates that there is ample household demand to support both existing and proposed project eating and drinking establishments.

Eating and drinking establishments located in closest proximity to the proposed project site—in Downtown Flushing and in the eastern part of North Corona—may be more likely than others in the Primary Trade Area to experience competitive pressure from proposed project establishments because residents who currently frequent those restaurants would be within walking distance or very short distance by car or public transit from the proposed project site. However, the potential for indirect displacement of groups of restaurants in both of these areas is limited. Downtown Flushing (Number 5 on **Figure 3-3**) has a unique shopping and dining

environment dominated by retail stores and restaurants that cater to Asian populations. This downtown area would retain its unique character and appeal with or without the addition of new eating and drinking establishments at the proposed project site. Retail concentrations in the eastern portion of North Corona (Number 1 on **Figure 3-3** and Numbers 3e and 3f on **Figure 3-4**) contain a mix of shoppers' goods stores, convenience goods stores, eating and drinking establishments, as well as industrial and commercial supply businesses. The eating and drinking establishments in this area are distributed across the commercial concentrations rather than clustered together in a way that would form a collective anchor. Most are small-scale restaurants and many are limited-service, which cater to the immediately surrounding residential communities, particularly the Hispanic community. Therefore it is unlikely that substantial numbers of existing restaurants in eastern North Corona would lose a meaningful proportion of retail sales to proposed project eating and drinking establishments.

Overall, existing restaurants in the immediate vicinity of the proposed project site distinguish themselves in different ways (e.g., a focus on ethnic populations, quick-serve limited-service, an established customer base, downtown setting). Many eating and drinking establishments in the area would likely benefit from the increased foot traffic resulting from the new proposed project residents, workers, and visitors, and local restaurants would not be significantly impacted by new eating and drinking establishments introduced as part of the proposed project. *

A. INTRODUCTION

This chapter examines the potential effects of the proposed project on community facilities in and around the project site. The 2012 *City Environmental Quality Review (CEQR) Technical Manual* defines community facilities as public or publicly funded facilities, including schools, health care, day care, libraries, and fire and police protection services. CEQR methodology focuses on direct impacts on community facilities and services and on increased demand for community facilities and services generated by new users, such as the population that would occupy a proposed residential development.

As described in Chapter 1, “Project Description,” Phases 1B and 2 of the proposed project would include a new public school with capacity that would meet the project-generated demand for school seats. The proposed project would not physically displace or alter an existing community facility. However, the project would introduce a substantial new residential population which could result in increased demand for community facilities and services.

The analysis updates changes in background conditions since the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda and assesses whether any changed background conditions and the differences in program elements between the proposed development program and those assessed during prior environmental review would result in any significant adverse impacts on community facilities and services that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

The analysis provided below regarding potential indirect effects to health care facilities and police and fire protection facilities concludes that—consistent with the conclusions of the 2008 FGEIS—the proposed project would not result in any significant adverse impacts on these community facilities and services.

The analysis of potential indirect effects on elementary, intermediate, and high schools finds that the proposed project would not result in any significant adverse impacts on high schools. In order to accommodate all of the project-generated elementary and intermediate school students, thereby avoiding any significant adverse impacts, the Queens Development Group, LLC (QDG) would coordinate with the School Construction Authority (SCA) to determine whether the public school space currently planned as part of Phase 1B would be sufficient to accommodate all of the school children generated by the proposed project by 2028. Provision of the school in Phase 1B would be ensured through a contractual agreement. If necessary, the school spaces would be expanded, and corresponding reductions in square footage would be made elsewhere in the development program. For Phase 2, the New York City Economic Development Corporation (EDC) would require as part of the developer’s agreement that the designated developer similarly coordinate with SCA.

The analysis of potential indirect effects on library services finds that the holdings per resident ratio for the combined study area would decrease from 3.03 under the No Action condition to 2.80 with the proposed project in 2032. This ratio would decrease to 5.02 for the Flushing Library and to 0.69 for the Corona Library. For both the Flushing Library and Corona Library, the catchment area population increase would exceed five percent, which may represent a significant adverse impact on library services according to the *CEQR Technical Manual*. However, as noted above, many of the residents in the catchment areas also reside within the catchment areas for other nearby libraries and would also be served by these libraries, residents of the study area would have access to the entire Queens Library system through the inter-library loan system, and would also have access to libraries near their places of work. In consideration of the above, the lead agency, in consultation with the Queens Public Library, has determined that the additional population introduced by the proposed project would impair the delivery of library services in the study area in 2032. Therefore, Phase 2 of the proposed project would result in a significant adverse impact on library services. To mitigate this impact, adequate space¹ within the 125,000 square feet of as-yet-unprogrammed community facility space in the program for Phase 2 could potentially would be made available to be utilized as a branch library or auxiliary facility for the Queens Library system, or additional volumes or programs to accommodate new users could be provided if adequate space in nearby branches exists. Although no developer has yet been designated for Phase 2, the provision of additional library space in Phase 2 would be based on further consultation with Queens Public Library and the lead agency.

The analysis of indirect effects on child care facilities finds that the proposed project may result in significant adverse impacts on publicly funded child care facilities in 2028. Therefore, consistent with the conclusions of the 2008 FGEIS, to mitigate the potential impact on child care facilities that could occur by 2028, the QDG (i) would consult with the New York City Administration for Child Services (ACS) to determine whether adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site is the appropriate way to meet demand for child care services generated by the proposed project; and (ii) would, as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site. EDC would require, as part of the developer's agreement, that the designated developer of Phase 2 similarly consult with ACS to determine the appropriate way to meet demand for child care services generated by development in the District by 2032 and would as directed by ACS, add capacity to existing facilities or provide a new child care facility within or near the area surrounding the project site.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS analyzed potential impacts on police services, fire services, and public elementary, intermediate, and high schools resulting from the development of the 2008 proposed Willets Point Development Plan and No Convention Center Scenario. The analysis of potential impacts to public schools considered elementary and middle schools within Zone 2 of Community School District 25 (CSD 25) as well as within a one-mile radius surrounding the District. The analysis of high schools considered the impact on the entire Borough of Queens. The analysis for libraries considered the 2008 proposed Willets Point Development Plan's

¹ In other projects, 15,000–20,000 square feet of community facility space has been adequate for the operation of a branch library.

impact on Flushing Library, the only library within a ¾-mile radius of the District. The analysis of health care facilities considered the 2008 proposed Willets Point Development Plan's impacts on Flushing Hospital Medical Center and the New York Hospital Center of Queens. The day care center analysis considered the 2008 proposed Willets Point Development Plan's impact on the nine publicly funded day care facilities within a one-mile radius of the District. An analysis of police and fire services considered the adequacy of emergency response times to the District.

The 2008 FGEIS found that the proposed Willets Point Development Plan would not result in any significant adverse impacts on public schools, libraries, health care facilities, or police or fire services. The analysis found that significant adverse impacts to day care centers could occur in 2017 as a result of either the Willets Point Development Plan or the No Convention Center Scenario. The 2008 FGEIS indicated that to mitigate the potential impact on day care facilities, EDC would require, as part of the developer's agreement, that a future developer consult with ACS to determine the appropriate way to meet demand for day care services generated by development in the District.

Subsequent technical memoranda revisited the analyses and findings from the 2008 FGEIS to determine whether project modifications, changes to background conditions, and changes in methodology for the analysis of potential impacts to community facilities would result in any significant adverse impacts that were not identified in the FGEIS. Key updates to data and methodology included: updated school enrollment and enrollment projections from the SCA (with Technical Memorandum #4 relying on school enrollment for the 2009-2010 school year and projections for the 2017-2018 school year); a shift in study areas used for analysis of public elementary and middle schools from the CSD level (used in the FGEIS) to the sub-district level (used in Technical Memorandum #4); updated CEQR generation rates for school-age children and child care-eligible children; updated enrollment and capacity information from ACS for child care facilities and Head Start programs (with Technical Memorandum #4 relying on data current as of October 2010); a shift in study areas used for the analysis of child care facilities from 1-mile (used in the 2008 FGEIS) to 1.5 miles (used in Technical Memorandum #4); and an expanded discussion of police, fire, and emergency services, per 2010 *CEQR Technical Manual* guidelines for projects that would result in the introduction of a sizeable new neighborhood.

The technical memoranda concluded that such changes would not result in any additional significant adverse impacts on any community facilities or services.

C. PRELIMINARY SCREENING

This analysis of community facilities has been conducted in accordance with 2012 *CEQR Technical Manual* guidelines and the latest data and guidance from agencies such as the New York City Department of Education (DOE), the New York Public Library (NYPL), and the New York City Department of City Planning (DCP).

The purpose of the preliminary screening is to determine whether a community facilities assessment is required. As recommended by the *CEQR Technical Manual*, a community facilities assessment is warranted if a project has the potential to result in either direct or indirect effects on community facilities. If a project would physically alter a community facility, whether by displacement of the facility or other physical change, this "direct" effect triggers the need to assess the service delivery of the facility and the potential effect that the physical change may have on that service delivery. New population added to an area as a result of a project would use existing services, which may result in potential "indirect" effects on service delivery. Depending

on the size, income characteristics, and age distribution of the new population, there may be effects on public schools, libraries, or child care centers.

DIRECT EFFECTS

The proposed project would not displace or otherwise directly affect any public schools, libraries, child care centers, health care facilities, or police and fire protection service facilities. Therefore an analysis of direct effects is not warranted.

INDIRECT EFFECTS

The *CEQR Technical Manual* provides thresholds for guidance in making an initial determination of whether a detailed analysis is necessary to determine potential impacts. **Table 4-1** lists those *CEQR Technical Manual* thresholds for each community facility analysis. If a proposal exceeds the threshold for a specific facility, a more detailed analysis is warranted. A preliminary screening analysis was conducted to determine if the proposed project would exceed established *CEQR Technical Manual* thresholds warranting further analysis. Based on that screening, a detailed analysis was undertaken for: public elementary, intermediate, and high schools; libraries; child care facilities; health care facilities; and police and fire protection services.

Table 4-1
Preliminary Screening Analysis Criteria

Community Facility	Threshold For Detailed Analysis
Public schools	More than 50 elementary/intermediate school or 150 high school students
Libraries	Greater than 5 percent increase in ratio of residential units to libraries in borough
Health care facilities (outpatient)	Introduction of sizeable new neighborhood where none existed before ¹
Child care centers (publicly funded)	More than 20 eligible children based on number of low- and low/moderate-income units by borough
Fire protection	Introduction of sizeable new neighborhood where none existed before ¹
Police protection	Introduction of sizeable new neighborhood where none existed before ¹
Notes: ¹ The <i>CEQR Technical Manual</i> cites the Hunter's Point South project as an example of a project that would introduce a sizeable new neighborhood where none existed before. The Hunter's Point South project would introduce approximately 6,650 new residential units to the Hunter's Point South waterfront in Long Island City, Queens.	
Source: <i>CEQR Technical Manual</i> .	

PUBLIC SCHOOLS

The *CEQR Technical Manual* recommends conducting a detailed analysis of public schools if a proposed action would generate more than 50 elementary/intermediate school students and/or more than 150 high school students. Based on the development of up to 5,850 residential units and the student generation rates provided by the *CEQR Technical Manual* (0.28 elementary, 0.12 intermediate, and 0.14 high school students per housing unit in Queens), the proposed project would generate approximately 3,159 total students—with approximately 1,638 elementary school students, 702 intermediate school students, and 819 high school students. This number of students warrants a detailed analysis of the proposed project's potential effects on elementary, intermediate, and high schools.

LIBRARIES

Potential impacts on libraries can result from an increased user population. According to the *CEQR Technical Manual*, a proposed action in Queens that generates a 5 percent increase in the average number of residential units served per branch (622 residential units in Queens) may cause a significant impact on library services and require further analysis. With up to 5,850 units, the proposed project exceeds this threshold, and a detailed analysis of libraries is warranted.

CHILD CARE CENTERS

According to the *CEQR Technical Manual*, if a proposed action would add more than 20 children eligible for publicly funded child care to the study area's child care facilities, a detailed analysis of its impact on publicly funded child care facilities is warranted. This threshold is based on the number of low-income and low/moderate-income units introduced by a proposed action.¹ In Queens, projects introducing 139 or more low- to moderate-income units would introduce 20 or more children eligible for publicly funded child care services. Because the proposed project is anticipated to introduce approximately 2,048 affordable housing units, a detailed child care analysis is warranted.

HEALTH CARE FACILITIES

Health care facilities include public, proprietary, and nonprofit facilities that accept government funds (usually in the form of Medicare and Medicaid reimbursements) and that are available to any member of the community. Examples of these types of facilities include hospitals, nursing homes, clinics, and other facilities providing outpatient health services.

According to the *CEQR Technical Manual*, if a proposed action would create a sizeable new neighborhood where none existed before, there may be increased demand on local public health care facilities, which may warrant further analysis of the potential for indirect impacts on outpatient health care facilities. The proposed project would result in the creation of a sizeable new neighborhood where none existed before. Therefore a detailed analysis of indirect effects on health care facilities is warranted.

POLICE AND FIRE SERVICES

The *CEQR Technical Manual* recommends detailed analyses of impacts on police and fire service in cases where a proposed action would affect the physical operations of, or direct access to and from, a precinct house or fire station, or where a proposed action would create a sizeable new neighborhood where none existed before. The proposed project would not result in these direct effects on either police or fire services, however it would create a sizeable new neighborhood where none existed before; therefore, a detailed analysis of indirect effects on police and fire services is warranted.

¹ Low-income and low/moderate-income are the affordability levels used in the *CEQR Technical Manual*. They are intended to approximate the financial eligibility criteria established by ACS, which generally corresponds to 200 percent of the Federal Poverty Level or 80 percent of area median income.

D. INDIRECT EFFECTS ON PUBLIC ELEMENTARY, INTERMEDIATE, AND HIGH SCHOOLS

METHODOLOGY

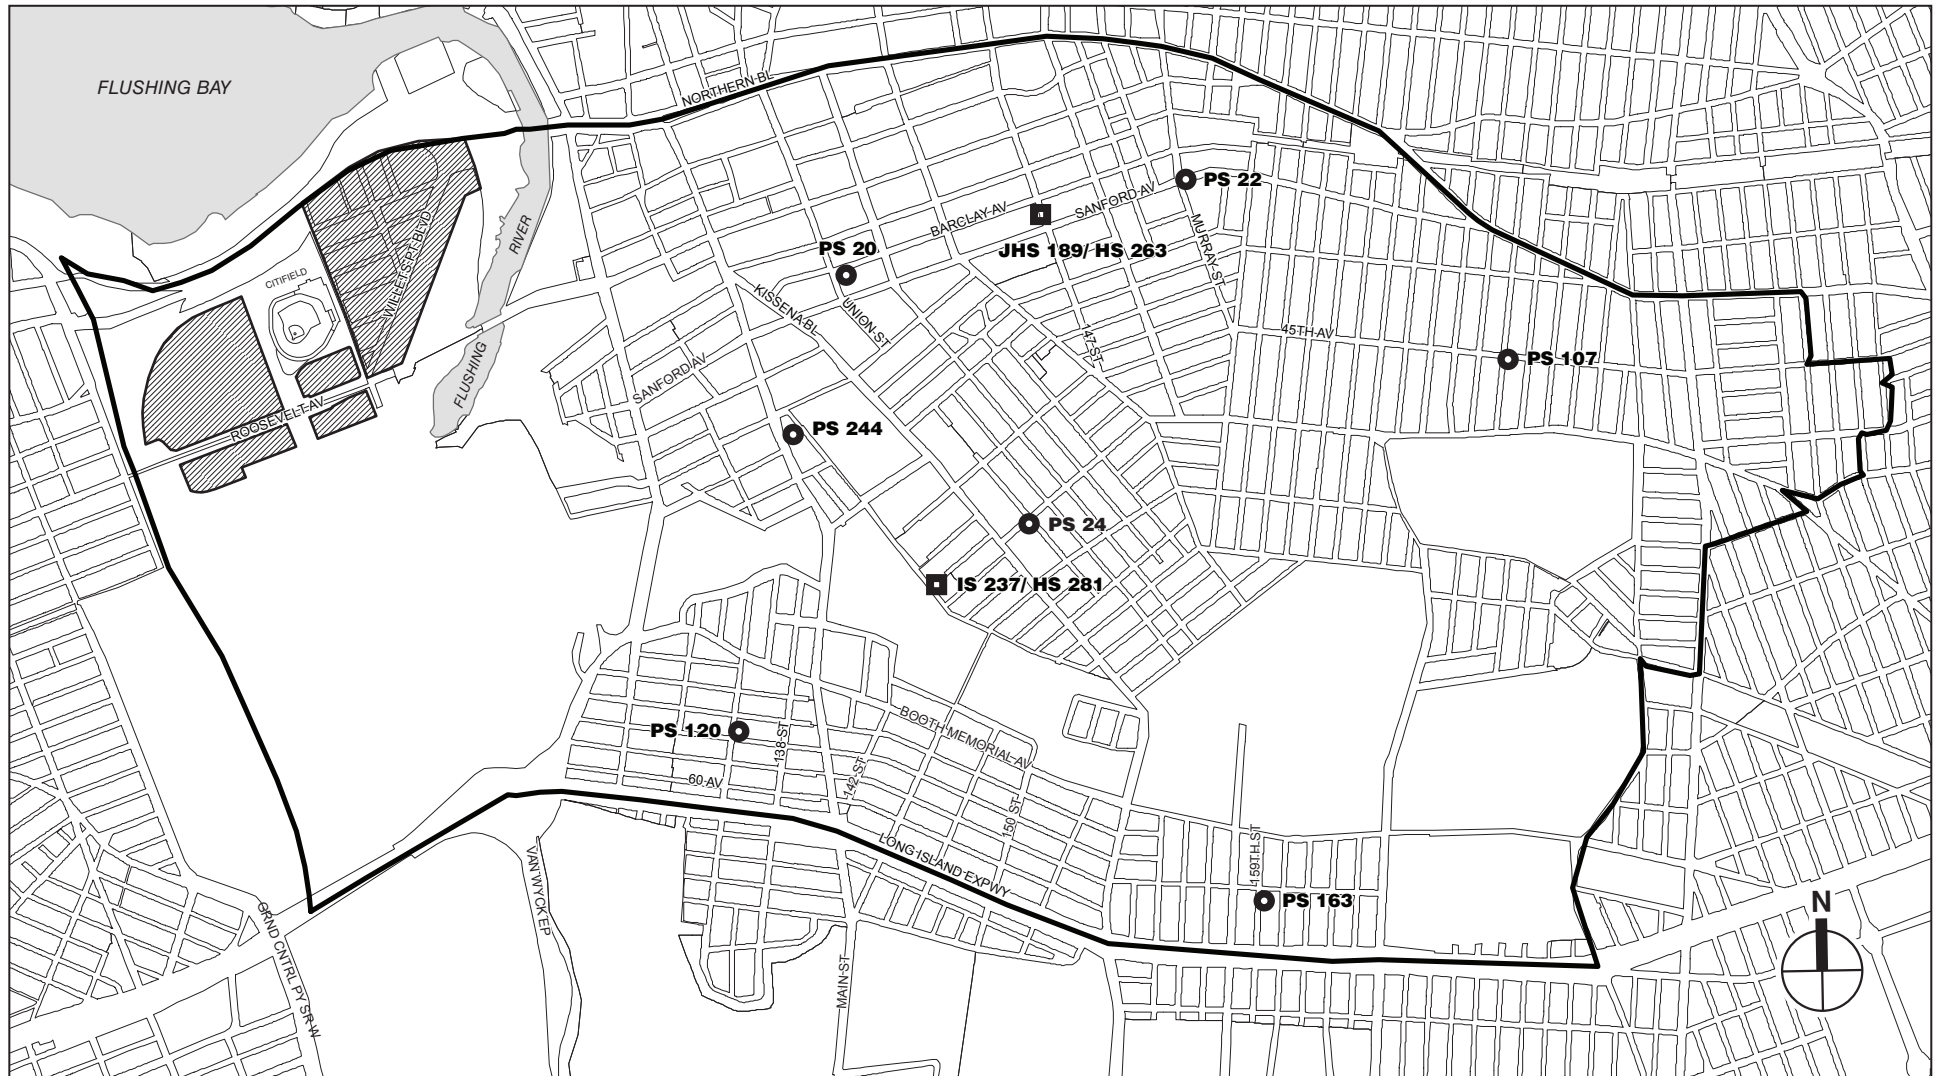

This analysis assesses the potential effects of the proposed project on public elementary, intermediate, and high schools serving the project site. Following methodologies in the *CEQR Technical Manual*, the study area for the analysis of elementary and intermediate schools is the school districts' "sub-district" (also known as "regions" or "school planning zones") in which the project is located. The proposed project site is located in Sub-district 2 of CSD 25 (see **Figure 4-1**). High school students routinely travel outside their neighborhoods for school; therefore, the *CEQR Technical Manual* provides for environmental review on a borough-wide basis.

As required by CEQR, this schools analysis uses the most recent DOE data on school capacity, enrollment, and utilization rates for elementary and intermediate schools in the sub-district study area and SCA projections of future enrollment. Specifically, the existing conditions analysis uses data provided in the DOE's *Utilization Profiles: Enrollment/Capacity/Utilization, 2011-2012* edition. Future conditions are then predicted based on SCA enrollment projections and data obtained from SCA's Capital Planning Division on the number of new housing units and students expected at the sub-district and borough levels. The future utilization rate for school facilities is calculated by adding the estimated enrollment from proposed residential developments in the schools' study area to DOE's projected enrollment, and then comparing that number with projected school capacity. DOE does not include charter school enrollment in its enrollment projections. DOE's enrollment projections for years 2009 through 2018, the most recent data currently available, are posted on the SCA website.¹ The latest available enrollment projections to 2018 have been used in this analysis to project student enrollment to 2032. These enrollment projections are based on broad demographic trends and do not explicitly account for discrete new residential developments planned for the study area. Therefore, the estimated student population from the other new development projects expected to be completed within the study area have been obtained from SCA's Capital Planning Division and are added to the projected enrollment to ensure a more conservative prediction of future enrollment and utilization. In addition, any new school projects identified in the DOE Five-Year Capital Plan are included if construction has begun.

The effect of the new students introduced by the proposed project on the capacity of schools within the study areas is then evaluated. According to the *CEQR Technical Manual*, a significant adverse impact may occur if a proposed action would result in both of the following conditions:

1. A utilization rate of the elementary and/or intermediate schools in the sub-district study area, or high schools in the borough study area, that is equal to or greater than 100 percent in the With Action condition; and
2. An increase of five percentage points or more in the collective utilization rate between the No Action and With Action conditions.

EXISTING CONDITIONS*ELEMENTARY SCHOOLS*

As shown in **Figure 4-1**, seven elementary schools serve CSD 25/Sub-District 2. As shown in **Table 4-2**, this sub-district has a total enrollment of 5,780 students, or 108 percent of capacity, with a shortage of 433 seats according to DOE's 2011-2012 school year enrollment figures, which are the most recent data currently available.

Table 4-2
Public Schools Serving the Special Willets Point District,
CSD 25 Sub-District 2 Enrollment and Capacity Data,
2010-2011 School Year

Name	Address	Enrollment	Capacity	Available Seats	Utilization

Notes: 1. See Figure 4-1 . 2. Capacity is the Target Capacity (assumes 20 children per class for grades K-3, 28 children per class for grades 4-8 and 30 children per class for grades 9-12). 3. Utilization rate equals school enrollment divided by capacity. Sources: SCA Utilization Profiles: Enrollment/Capacity/Utilization, 2011-2012.					

INTERMEDIATE SCHOOLS

As shown in **Figure 4-1** and **Table 4-2**, three intermediate schools serve CSD 25/Sub-District 2. Total enrollment at these intermediate schools is 2,240 students, or 104 percent of capacity, with a shortage of 96 seats.

HIGH SCHOOLS

High school students may attend any of the schools within any borough of the city, based on seating availability and admissions criteria.

Willets Point Development

Throughout Queens, total high school enrollment for the 2011–2012 school year was approximately 84,225 students, with an overall utilization rate of 110 percent, and a shortage of 7,701 seats. There are two high schools located within CSD 25/Sub-District 2, which are listed below in **Table 4-2** and shown in **Figure 4-1** for informational purposes.

THE FUTURE WITHOUT THE PROPOSED PROJECT

ENROLLMENT PROJECTIONS

As required by CEQR, the assessment of No Action conditions uses SCA enrollment projections. SCA provides future enrollment projections by district for up to 10 years. The latest available enrollment projections to 2018 have been used in this analysis to project student enrollment for the proposed project's three build years (2018, 2028, and 2032). SCA projects that elementary enrollment will increase by 54 percent in CSD 25/Sub-District 2. Intermediate enrollment in the sub-district will increase by 6 percent, and high school enrollment in Queens will decrease by 14 percent.

These enrollment projections focus on the natural growth of the city's student population (through births and grade retention) and do not account for new residential developments planned for the sub-district study areas (No Action projects). Therefore, the future utilization rate for school facilities is calculated by adding the estimated enrollment from proposed residential developments in the school study areas (as provided by SCA's Capital Planning Division) to SCA's projected enrollment, and then comparing that number with projected school capacity.

Table 4-3 outlines the estimated number of new public elementary, intermediate, and high school students generated as a result of development in the No Action condition, which has been provided by SCA, and is based on student generation rates listed in Table 6-1a of the *CEQR Technical Manual* (0.28 elementary students, 0.12 intermediate school students, and 0.14 high school students per residential unit in Queens).

Table 4-3
Projected Estimated Number of New Students
Introduced by Development in the No Action Condition

Study Area	Projected New Students		
	Elementary	Intermediate	High School
Sub-district 2 of CSD 25	783	336	N/A
Borough of Queens	N/A	N/A	4,310 ⁽¹⁾
Notes: ⁽¹⁾ Does not include Halletts Point Rezoning, which would introduce 2,573 housing units (estimated 360 high school students) to Astoria, Queens.			
Source: SCA Capital Planning Division.			

PROJECTED SCHOOL CAPACITY

According to the DOE *Proposed 2010-2014 Five-Year Capital Plan—February 2013 Amendment*, there is no new school capacity under construction within the study area. However, future capital plans may include additional schools, if needed, to service the area.

ANALYSIS

The most current DOE enrollment projections extend to 2018, and the most current DOE capital plan extends to 2014. Therefore, these 2014 and 2018 figures are used as the basis for No Build conditions for all three of the proposed project's build years—2018, 2028, and 2032. For the

analysis of high schools, estimated enrollment from the planned Halletts Point rezoning was added to the base figures from DOE. The Halletts Point rezoning project is anticipated to introduce approximately 2,573 housing units (an estimated 360 high school students) to the Astoria neighborhood of Queens and is not included in DOE's estimation of future enrollment.

Elementary Schools

As shown in **Table 4-4**, elementary schools in CSD 25/Sub-District 2 will be over capacity in the No Action condition in 2018, 2028, and 2032. The sub-district will operate at 188 percent utilization, with a deficit of 4,554 seats.

Table 4-4
Estimated Public School Enrollment, Capacity, and Utilization:
No Action Condition (2018, 2028, and 2032)

Study Area	Projected Enrollment ¹	Students Introduced by Residential Development in No Action	Total No Action Enrollment	Capacity	Available Seats	Utilization
Elementary Schools (2018, 2028, and 2032)						
Sub-district 2 of CSD 25	8,969	783 ⁽²⁾	9,752	5,198	-4,554	188%
Intermediate Schools (2018, 2028, and 2032)						
Sub-district 2 of CSD 25	2,397	336 ⁽²⁾	2,733	2,159	-575	127%
High Schools (2018)						
Borough of Queens	72,053	4,310 ⁽³⁾	76,363	77,997 ⁽⁴⁾	1,634	98%
High Schools (2028 and 2032)						
Borough of Queens	72,053	4,670 ⁽⁵⁾	76,724	77,997 ⁽⁴⁾	1,273	98%
Notes: ¹ Elementary and intermediate school enrollment in each sub-district study area was calculated by applying SCA supplied percentages for each sub-district to the relevant district enrollment projections. For CSD 25/Sub-District 2, the district's 2018 elementary projection of 24,220 was multiplied by 37.03 percent. The sub-district's intermediate projection of 8,207 was multiplied by 29.21 percent. High school enrollment utilizes the 2018 projection of 72,053. ² Based on the number of additional students expected within the sub-district in the future without the proposed project (obtained from SCA). ³ Based on enrollment estimates for projected housing starts in CSD 24-30 (from SCA's <i>Projected New Housing Starts as Used in 2009-2018 Enrollment Projection</i>). ⁴ High school capacity for Queens includes 1,473 high school seats in construction or completed in Queens according to the 2010–2014 Capital Plan, which includes projected high school capacity in IS/HS 404. ⁵ Includes 360 high school students anticipated as a result of the Halletts Point Rezoning project, which would introduce approximately 2,576 housing units to Astoria, Queens. Sources: DOE <i>Enrollment Projections 2009-2018 by the Grier Partnership</i> ; DOE, <i>Utilization Profiles: Enrollment/Capacity/Utilization, 2011-2012</i> ; DOE 2010-2014 <i>Five-Year Capital Plan, Amendment</i> , February 2013; School Construction Authority.						

Intermediate Schools

As shown in **Table 4-4**, intermediate schools in CSD 25/Sub-District 2 will be over capacity in the No Action condition in 2018, 2028, and 2032. The sub-district will operate at 127 percent utilization, with a deficit of 575 seats.

High Schools

As shown in **Table 4-4**, high schools in Queens will be operating at approximately 98 percent capacity in 2018, 2028, and 2032, with a surplus of 1,634 seats in 2018, and a surplus of 1,273 seats in 2028 and 2032.

PROBABLE IMPACTS OF THE PROPOSED PROJECT

The proposed project would develop a total of 5,850 residential units, with 2,490 to be completed by 2028 and another 3,360 to be completed by 2032. Student generation and school utilization levels are discussed below for each of the proposed project's three build years.

Willets Point Development

PHASE IA (2018)

The proposed project would not result in any new residential development by 2018; therefore utilization rates would remain the same as in the No Action condition.

PHASE IB (2028)

By 2028, the proposed project would add approximately 2,490 residential units to the study area. Based on the CEQR student generation rates, the proposed project would introduce approximately 697 elementary school students, 299 intermediate school students, and 349 high school students into the study area by 2028 (see **Table 4-5**).

Table 4-5
Estimated Number of Students Introduced in Sub-district 2 of CSD 25:
With Action Condition, 2018, 2028, 2032

Development Phase (Year)	Housing Units	Elementary Students	Intermediate Students	High School Students
Phase IA (2018)	0	0	0	0
Phase IB (2028)	2,490	697	299	349
Phase 2 (2032)	3,360	941	403	470
Total	5,850	1,638	702	819

Sources: CEQR Technical Manual, Table 6-1a.

As described in Chapter 1, “Project Description,” Phase 1B of the proposed project would include a public school (grades kindergarten through eighth) of approximately 105,000 square feet, subject to approvals and requirements of SCA. Provision of the school in Phase 1B would be ensured through a contractual agreement. Preliminary discussions have been held among QDG, EDC, and SCA with regard to the development terms of a new K-Grade 8 facility that would address the Phase 1B project-generated school seat demand. It is expected that at a minimum QDG will provide the core and shell of the building and may provide additional fit-out of the facility. If SCA must provide some or all of the costs of the fit-out of the school, funds would need to be provided from the SCA capital budget. QDG would coordinate with SCA to determine whether the school as currently planned would accommodate all of the project-generated elementary and intermediate students (996 students). If necessary, the school would be expanded, and corresponding reductions in square footage would be made elsewhere in the development program. Therefore, the Phase 1B school would accommodate all project-generated demand for elementary and intermediate school seats.

Elementary Schools

In 2028 with the proposed project, 10,449 students would be enrolled at elementary schools within Sub-district 2 of CSD 25. Phase 1B of the proposed project includes the development of a new public school (serving kindergarten through eighth grades) that would accommodate the elementary school students generated by the proposed project. Taking into account both the project-generated elementary students and the proposed project school, elementary schools within Sub-district 2 of CSD 25 would have capacity for 5,895 students and operate at 177 percent, with a shortfall of 4,554 seats.

As noted above, a significant adverse impact may occur if a proposed action would result in both of the following conditions: (1) a utilization rate of the elementary schools in the sub-district study area that is equal to or greater than 100 percent in the future without the proposed action;

and (2) an increase of five percentage points or more in the collective utilization rate between the future without the proposed action and future with the proposed action conditions. With the development of the proposed public school in the District, the proposed project would introduce enough capacity to accommodate all Phase 1B project-generated elementary school students. As a result, the proposed project would decrease the elementary school utilization rate by 11 percentage points (from 188 percent in the No Action condition to 177 percent with the proposed project). Because the proposed project would not increase the elementary school utilization rate, the proposed project would not result in a significant adverse impact on elementary schools in the study area in 2028.

Intermediate Schools

In 2028 with the proposed project, 3,032 students would be enrolled at intermediate schools within Sub-district 2 of CSD 25. As indicated above, Phase 1B of the proposed project includes the development of a new public school that would accommodate the intermediate school students generated by the proposed project. Taking into account the project-generated students and new seats, intermediate schools within Sub-district 2 of CSD 25 would have capacity for 2,458 students and operate at 123 percent, with a shortfall of 575 seats (see **Table 4-6**).

Table 4-6
Estimated Public School Enrollment, Capacity, and Utilization:
With Action Condition, 2028

Study Area	No Action Enrollment	Students Introduced by Phase 1B	Total With Action Enrollment	Capacity	Available Seats	Utilization	Change in Utilization Compared with No Action
Elementary Schools							
Sub-district 2 of CSD 25	9,752	697	10,449	5,895	-4,554	177%	-11%
Intermediate Schools							
Sub-district 2 of CSD 25	2,733	299	3,032	2,458	-575	123%	-4%
High Schools							
Borough of Queens	76,724	349	77,073	77,997	924	98%	0%
Sources: DOE Enrollment Projections 2009-2018 by the Grier Partnership; DOE, Utilization Profiles: Enrollment/Capacity/Utilization, 2011-2012; DOE 2010-2014 Five-Year Capital Plan, Amendment, February 2013; School Construction Authority.							

With the development of the proposed public school in the District, the proposed project would introduce enough capacity to accommodate all Phase 1B project-generated intermediate school students. As a result, the proposed project would decrease the intermediate school utilization rate by four percentage points (from 127 percent in the No Action condition to 123 percent with the proposed project). Because the proposed project would not increase the intermediate school utilization rate, the proposed project would not result in a significant adverse impact on intermediate schools in the study area in 2028.

High Schools

In the 2028 With Action condition, the total enrollment of high school students in Queens would increase by 349 students to 77,073 (98 percent utilization), resulting in a surplus of 924 seats. The new high school students introduced by the proposed project would increase utilization in the borough by less than one percent over the No Action condition (see **Table 4-6**). As the proposed project would not increase the utilization rate by 5 percent at the borough level, it would not result in a significant adverse impact on high schools in 2028.

Willels Point Development

PHASE 2 (2032)

Phase 2 of the proposed project would add another approximately 3,360 residential units to the District, bringing the total number of proposed project units to 5,850. Based on the CEQR student generation rates, the proposed project would introduce approximately 941 elementary school students, 403 intermediate school students, and 470 high school students into the study area during Phase 2, bringing the total number of project-generated students to 1,638 elementary students, 702 intermediate students, and 819 high school students (see **Table 4-7**).

Table 4-7

**Estimated Public Elementary and Intermediate School Enrollment, Capacity, and Utilization:
With Action Condition, 2032**

Study Area	No Action Enrollment	Students Introduced by Phase 2	Total With Action Enrollment	Capacity	Available Seats	Utilization	Change in Utilization Compared with No Action
Elementary Schools							
Sub-district 2 of CSD 25	9,752	1,638	11,390	6,836	-4,554	167%	-22%
Intermediate Schools							
Sub-district 2 of CSD 25	2,733	702	3,435	2,861	-575	120%	-7%
High Schools							
Borough of Queens	76,724	819	77,543	77,997	454	99%	1%
Sources: DOE Enrollment Projections 2009-2018 by the Grier Partnership; DOE, Utilization Profiles: Enrollment/Capacity/Utilization, 2011-2012; DOE 2010-2014 Five-Year Capital Plan, Amendment, February 2013; School Construction Authority.							

As described in Chapter 1, “Project Description,” Phase 2 of the proposed project would include a school of approximately 125,000 square feet, separate from the 105,000 square foot public school to be developed within the District during Phase 1B. Provision of the school would be ensured through contractual agreement with the future designated developer for Phase 2. The designated developer for Phase 2 would be required by EDC to coordinate with SCA to determine whether the school as currently planned would accommodate all of the Phase 2 project-generated elementary and intermediate students. Therefore, the schools developed in Phase 1B and Phase 2 would accommodate all project-generated demand for elementary and intermediate school seats.

Elementary Schools

In 2032 with the proposed project, 11,390 students would be enrolled at elementary schools within Sub-district 2 of CSD 25. As described above, Phase 2 of the proposed project would add another school, separate from the public school built during Phase 1B, accommodating the additional elementary school students that would be generated by Phase 2 of the project. Accounting for both the project-generated elementary students and the proposed project Phase 2 school addition, elementary schools within Sub-district 2 of CSD 25 would have capacity for 6,836 students and operate at 167 percent, with a shortfall of 4,554 seats.

Because the proposed project would introduce enough capacity to accommodate all Phase 2 project-generated elementary school students, the proposed project would decrease the intermediate school utilization rate by 21 percentage points (from 188 percent in the No Action condition to 166 percent with the proposed project). Because the proposed project would not increase the elementary school utilization rate, the proposed project would not result in a significant adverse impact on elementary schools in the study area in 2032.

Intermediate Schools

In 2032 with the proposed project, 3,435 students would be enrolled at intermediate schools within Sub-district 2 of CSD 25. The Phase 2 proposed school would accommodate the intermediate school students generated by Phase 2 of the proposed project. Taking into account the project-generated students and new seats, intermediate schools within Sub-district 2 of CSD 25 would have capacity for 2,861 students and operate at 120 percent, with a shortfall of 575 seats (see **Table 4-7**).

With the development of the proposed public school in the District, the proposed project would introduce enough capacity to accommodate all Phase 2 project-generated intermediate school students. As a result, the proposed project would decrease the intermediate school utilization rate by seven percentage points (from 127 percent in the No Action condition to 120 percent with the proposed project). Because the proposed project would not increase the intermediate school utilization rate, the proposed project would not result in a significant adverse impact on intermediate schools in the study area in 2032.

High Schools

Phase 2 of the proposed project would generate an additional 470 high school students, bringing the total enrollment of high school students in Queens to 77,543 (99% utilization) in 2032, resulting in a surplus of 454 seats. The new high school students introduced by the proposed project would increase utilization in the borough by one percent over the No Action condition (see **Table 4-7**). As the proposed project would not increase the utilization rate by 5 percent at the borough level, it would not result in a significant adverse impact on high schools in 2032.

E. INDIRECT EFFECTS ON LIBRARIES

METHODOLOGY

According to the *CEQR Technical Manual*, service areas for neighborhood branch libraries are based on the distance that residents would travel to use library services, typically not more than $\frac{3}{4}$ mile (this is referred to as the library's "catchment area"). This libraries analysis compares the population generated by the proposed project with the catchment area population of libraries available within an approximately $\frac{3}{4}$ -mile area around the project site.

To determine the existing population of each library's catchment area, 2010 U.S. Census data were assembled for all census tracts that fall primarily within $\frac{3}{4}$ -mile of each library. The catchment area population in the No Action condition was estimated by multiplying the number of new residential units in No Action projects located within the $\frac{3}{4}$ -mile catchment area by an average household size of 2.82 persons.¹ The catchment area population in the With Action condition was estimated by adding the anticipated population that would result from development on the project site.

New population in the No Action and With Action conditions was added to the existing catchment area population. According to the *CEQR Technical Manual*, if a proposed project would increase the libraries' catchment area population by 5 percent or more, and this increase would impair the delivery of library services in the study area, a significant impact could occur.

¹ Census 2000, average household size for Queens.

EXISTING CONDITIONS

The project site is served by the Queens Library system, which serves all of Queens. The Queens Library is an autonomous library system, guided by a 19-member Board of Trustees appointed by the Mayor of the City of New York and the Queens Borough President. The system serves a population of 2.3 million from 62 locations and seven Adult Learning Centers. It circulates among the highest numbers of books and other library materials in the country.

The Flushing Library and the Corona Library are the two branches of the Queens Library system located within ¾-mile of the project site (see **Table 4-8** and **Figure 4-2**).

Table 4-8
Public Libraries Serving the Project Site

Map No. ⁽¹⁾	Library Name	Address	Holdings	Catchment Area Population	Holdings per Resident
1	Flushing Library	41-17 Main Street	530,000	80,493	6.58
2	Corona Library	38-23 104th	91,613	115,148	0.80
Total:			621,613	195,641	3.18
3	Mitchell-Linden Library	29-42 Union Street	85,161	26,160	3.26

Notes:
⁽¹⁾ Please refer to **Figure 4-2** for library locations. Mitchell-Linden Library is located outside of the study area boundary.
⁽²⁾ The catchment area population for each library includes the area within ¾-mile of the library.

Sources: Queens Library; U.S. Census Bureau, 2010 Census, NYC DCP Selected Facilities and Program Sites.

The Flushing Library is located to the east of the project site, near downtown Flushing, at the intersection of Kissena Boulevard and Main Street. In addition to a wide selection of fiction and nonfiction books, periodicals, and audio-visual media, the Flushing Library has a job information center, an international language collection that includes 12 languages ranging from French to Urdu, and 60 computers for public Internet access. Users of the Flushing Library can request a volume from any of the other libraries in the Queens Library system through inter-library loan.

The Corona Library is located west of the project site, on 104th Street in North Corona. It offers a range of books, periodicals, and audio-visual media, and offers free computer classes, as do all branches of the Queens Library.

Table 4-8 above provides the catchment area population for the Flushing and Corona Libraries and the total catchment area population served by the two libraries. Combined, the two libraries in the study area have a total of approximately 621,613 holdings. With a catchment area population of 195,641, the combined catchment area has a holdings-to-resident ratio of 3.18.

In addition, the Mitchell-Linden Library is located just beyond the study area boundary (see **Figure 4-2**). Residents in the northeastern portion of the study area would be likely to use this branch in addition to the services provided by the Flushing Library. The Mitchell-Linden Library has approximately 85,161 holdings. With a catchment area population of 26,160, the Mitchell-Linden Library has a holdings-to-resident ratio of 3.26.

THE FUTURE WITHOUT THE PROPOSED PROJECT

In the No Action condition, the two existing libraries will continue to serve the study area. No changes to the holdings of these facilities are expected for the purpose of this analysis.

The catchment area population of each library will increase as a result of development projects completed in the No Action condition, all of which are expected to be complete by 2018.

Overall, new residential units will introduce approximately 9,814 new residents to the catchment areas by 2018, increasing the catchment area population to 205,455. As shown in **Table 4-9**, the holdings-per-resident ratio will decrease by approximately 0.63 for the Flushing Library and 0.01 for the Corona Library. Overall, the holdings-per-resident ratio for both catchment areas combined will decrease from 3.18 to 3.03.

Table 4-9
No Action Condition (2018, 2028, and 2032):
Catchment Area Population

Library Name	Existing Catchment Area Population	New Residents in the No Action Condition	New Catchment Area Population	New Holdings per Resident in the No Action Condition
Flushing Library	80,493	8,590	89,083	5.95
Corona Library	115,148	1,224	116,372	0.79
TOTAL	195,641	9,814	205,455	3.03
Note: ¹ The catchment area population for each library includes the area within ¼ mile of the library.				
Sources: Queens Library; U.S. Census Bureau, 2010 Census, AKRF, Inc.				

PROBABLE IMPACTS OF THE PROPOSED PROJECT

According to the *CEQR Technical Manual*, if a proposed project increases the study area population by 5 percent or more as compared with the No Action condition, this increase may impair the delivery of library services in the study area, and a significant adverse impact could occur.

PHASE 1A (2018)

The proposed project would not result in any new residential development by 2018; therefore the holdings-per-resident ratios would remain the same as in the No Action condition.

PHASE 1B (2028)

By 2028, Phase 1B of the proposed project would introduce a total of 2,490 residential units, which would add approximately 7,022 residents to the library study area. **Table 4-10** provides the population increase and the change in the holding-per-resident ratio for the Flushing Library and Corona Library catchment areas and the combined catchment area for the two libraries. The figures presented for each of the individual libraries conservatively add the entire proposed project population to the catchment area population for that particular library. The figures presented as totals add the proposed project population to the population for the combined catchment area population for the two libraries, resulting in a lower percent increase in population.

Table 4-10
Phase 1B (2028) With Action Condition: Catchment Area Population

Library Name	Catchment Area Population – No Action Condition	Population Increase due to the Proposed Project	Catchment Area Population – With Action Condition	Population Increase	Holdings per Resident – With Action Condition
Flushing Library	89,083	7,022	96,105	7.9%	5.51
Corona Library	116,372	7,022	123,394	6.0%	0.74
TOTAL	205,455	7,022	212,476	3.4%	2.93
Note: The catchment area population for each library includes the area within ¼ mile of the library.					
Sources: Queens Library; U.S. Census Bureau, 2010 Census, AKRF, Inc.					

Willels Point Development

With this additional population, the Flushing Library would serve 96,105 residents (a 7.9 percent increase) and the Corona Library would serve 123,394 residents (a 6.0 percent increase). The population of the combined catchment area would increase 3.4 percent to 212,476.

Overall, the holdings per resident ratio for the combined study area would decrease from 3.03 under the No Action condition to 2.93 with the proposed project in 2028. This ratio would decrease to 5.51 for the Flushing Library and to 0.74 for the Corona Library. For both the Flushing Library and Corona Library, the catchment area population increase would exceed 5 percent, which may represent a significant adverse impact on library services according to the *CEQR Technical Manual*. However, many of the residents in the catchment areas also reside within the catchment areas for other nearby libraries, such as the Langston Hughes Library (which is approximately 0.5 miles from the Corona Library) and the Mitchell Linden Library (which is approximately 0.8 miles from the Flushing Library), and would also be served by these libraries. Residents of the study area would have access to the entire Queens Library system through the inter-library loan system and could have volumes delivered directly to their nearest library branch. In addition, residents would also have access to libraries near their place of work. Lastly, the program for Phase 1B provides for 25,000 square feet of as-yet-unprogrammed community facility space which could potentially be utilized as a branch library or auxiliary facility for the Queens Library system. Therefore, the population introduced by the proposed project would not impair the delivery of library services in the study area, and the proposed project would not result in any significant adverse impacts on public libraries in 2028.

PHASE 2 (2032)

By 2032, the proposed project would introduce a total of 5,850 residential units, which would add approximately 16,497 residents to the library study area. **Table 4-11** provides the population increase and the change in the holding-per-resident ratio for the Flushing Library and Corona Library catchment areas and the combined catchment area for the two libraries. The figures presented for each of the individual libraries conservatively add the entire proposed project population to the catchment area population for that particular library. The figures presented as totals add the proposed project population to the population for the combined catchment area population for the two libraries, resulting in a lower percent increase in population.

Table 4-11
Phase 2 (2032) With Action Condition: Catchment Area Population

Library Name	Catchment Area Population – No Action Condition	Population Increase due to the Proposed Project	Catchment Area Population – With Action Condition	Population Increase	Holdings per Resident – With Action Condition
Flushing Library	89,083	16,497	105,580	18.5%	5.02
Corona Library	116,372	16,497	132,869	14.2%	0.69
TOTAL	205,455	16,497	221,952	8.0%	2.80
Note: The catchment area population for each library includes the area within ¼ mile of the library.					
Sources: Queens Library; U.S. Census Bureau, 2010 Census, AKRF, Inc.					

With this additional population, the Flushing Library would serve 105,580 residents (an 18.5 percent increase) and the Corona Library would serve 132,869 residents (a 14.2 percent increase). The population of the combined catchment area would increase 8.0 percent to 221,952.

Overall, the holdings per resident ratio for the combined study area would decrease from 3.03 under the No Action condition to 2.80 with the proposed project in 2032. This ratio would decrease to 5.02 for the Flushing Library and to 0.69 for the Corona Library. For both the Flushing Library and Corona Library, the catchment area population increase would exceed five percent, which may represent a significant adverse impact on library services according to the *CEQR Technical Manual*. However, as noted above, many of the residents in the catchment areas also reside within the catchment areas for other nearby libraries and would also be served by these libraries, residents of the study area would have access to the entire Queens Library system through the inter-library loan system, and would also have access to libraries near their places of work. In consideration of the above, the lead agency, in consultation with the Queens Public Library, has determined that the additional population introduced by the proposed project would impair the delivery of library services in the study area in 2032. Therefore, Phase 2 of the proposed project would result in a significant adverse impact on library services. To mitigate this impact, adequate space¹ within the 125,000 square feet of as-yet-unprogrammed community facility space in the program for Phase 2 ~~would be made available to could potentially~~ be utilized as a branch library or auxiliary facility for the Queens Library system, or additional volumes or programs to accommodate new users could be provided if adequate space in nearby branches exists. Although no developer has yet been designated for Phase 2, the provision of additional library space in Phase 2 would be based on further consultation with Queens Public Library and the lead agency.

F. INDIRECT EFFECTS ON CHILD CARE SERVICES

METHODOLOGY

ACS provides subsidized child care services through center-based group child care, family-based child care, informal child care, and Head Start. Publicly-financed child care services are available for income-eligible children up to the age of 12. In order for a family to receive subsidized child care services, the family must meet specific financial and social eligibility criteria that are determined by federal, state, and local regulations. In general, children in families that have incomes at or below 200 percent of the Federal Poverty Level (FPL), depending on family size, are financially eligible, although in some cases eligibility can go up to 275 percent FPL. The family must also have an approved “reason for care,” such as involvement in a child welfare case or participation in a “welfare-to-work” program. Head Start is a federally-funded child care program that provides children with half-day or full-day early childhood education; program eligibility is limited to families with incomes 130 percent or less of the FPL.

Most children are served through contract with private and nonprofit organizations that operate child care programs throughout the city. Registered or licensed providers can offer family-based child care in their homes. Informal child care can be provided by a relative or neighbor for no more than two children. Children aged two months through 12 years old can be cared for either in group child care centers licensed by the Department of Health (DOH) or in homes of registered child care providers. ACS also issues vouchers to eligible families, which may be used by parents to pay for child care from any legal child care provider in the City.

Publicly-financed child care centers, under the auspices of the New York City Division for Child Care and Head Start (CCHS) within ACS, provide care for the children of income-eligible households. Space for one child in such child care centers is termed a “slot.” These slots may be in group child care

¹ In other projects, 15,000–20,000 square feet of community facility space has been adequate for the operation of a branch library.

or Head Start centers, or they may be in the form of family-based child care in which 7 to 12 children are placed under the care of a licensed provider and an assistant in a home setting.

Since there are no locational requirements for enrollment in child care centers, and some parents or guardians choose a child care center close to their employment rather than their residence, the service areas of these facilities can be quite large and are not subject to strict delineation in order to identify a study area. However, according to the current methodology for child care analyses in the *CEQR Technical Manual*, the locations of publicly funded group child care centers within 1½ miles or so of the project site should be shown, reflecting the fact that the centers closest to the project site are more likely to be subject to increased demand. Current enrollment data for the child care and Head Start centers closest to the project site was gathered from ACS.

The child care enrollment in the No Action condition was estimated by multiplying the number of new low-income and low/moderate-income housing units expected in the 1½-mile study area by the *CEQR Technical Manual* multipliers for estimating the number of children under age six eligible for publicly funded child care services (Table 6-1b). For Queens, the multiplier estimates 0.140 public child care-eligible children under age six per low- and low/moderate-income household.¹ The estimate of new public child care-eligible children was added to the existing child care enrollment to estimate enrollment in the No Action condition.

The child care-eligible population introduced by the proposed project was also estimated using the *CEQR Technical Manual* child care multipliers. The population of children under age six eligible for publicly funded child care was then added to the child care enrollment calculated in the No Action condition. According to the *CEQR Technical Manual*, if a proposed action would result in a demand for slots greater than remaining capacity of child care centers, and if that demand constitutes an increase of 5 percent or more of the collective capacity of the child care centers serving the area of the proposed action, a significant adverse impact may result.

EXISTING CONDITIONS

There are seven publicly funded group child care facilities and five Head Start facilities within the study area (see **Figure 4-3**). The child care and Head Start facilities have a total capacity of 837 slots and have 21 available slots (97 percent utilization). **Table 4-12** shows the current capacity and enrollment for these facilities. Family-based child care facilities and informal care arrangements provide additional slots in the study area, but these slots are not included in the quantitative analysis.

THE FUTURE WITHOUT THE PROPOSED PROJECT

In the No Action condition, known planned or proposed development projects will introduce approximately 543 new affordable housing units, all of which are expected to be complete by 2018.² Based on the CEQR generation rates for the projection of children eligible for publicly funded child care multipliers, this amount of development would introduce approximately 76 new children under the age of six who would be eligible for publicly funded child care programs.

¹ Low-income and low/moderate-income are the affordability levels used in the *CEQR Technical Manual*. They are intended to approximate the financial eligibility criteria established by ACS, which generally corresponds to 200 percent of FPL or 80 percent of AMI.

² Assumes that 20 percent of units in developments of 20 or more units would be occupied by low- or low/moderate-income households meeting the financial and social criteria for publicly funded child care. Excludes the Sky View Parc project, which will include luxury condominiums.

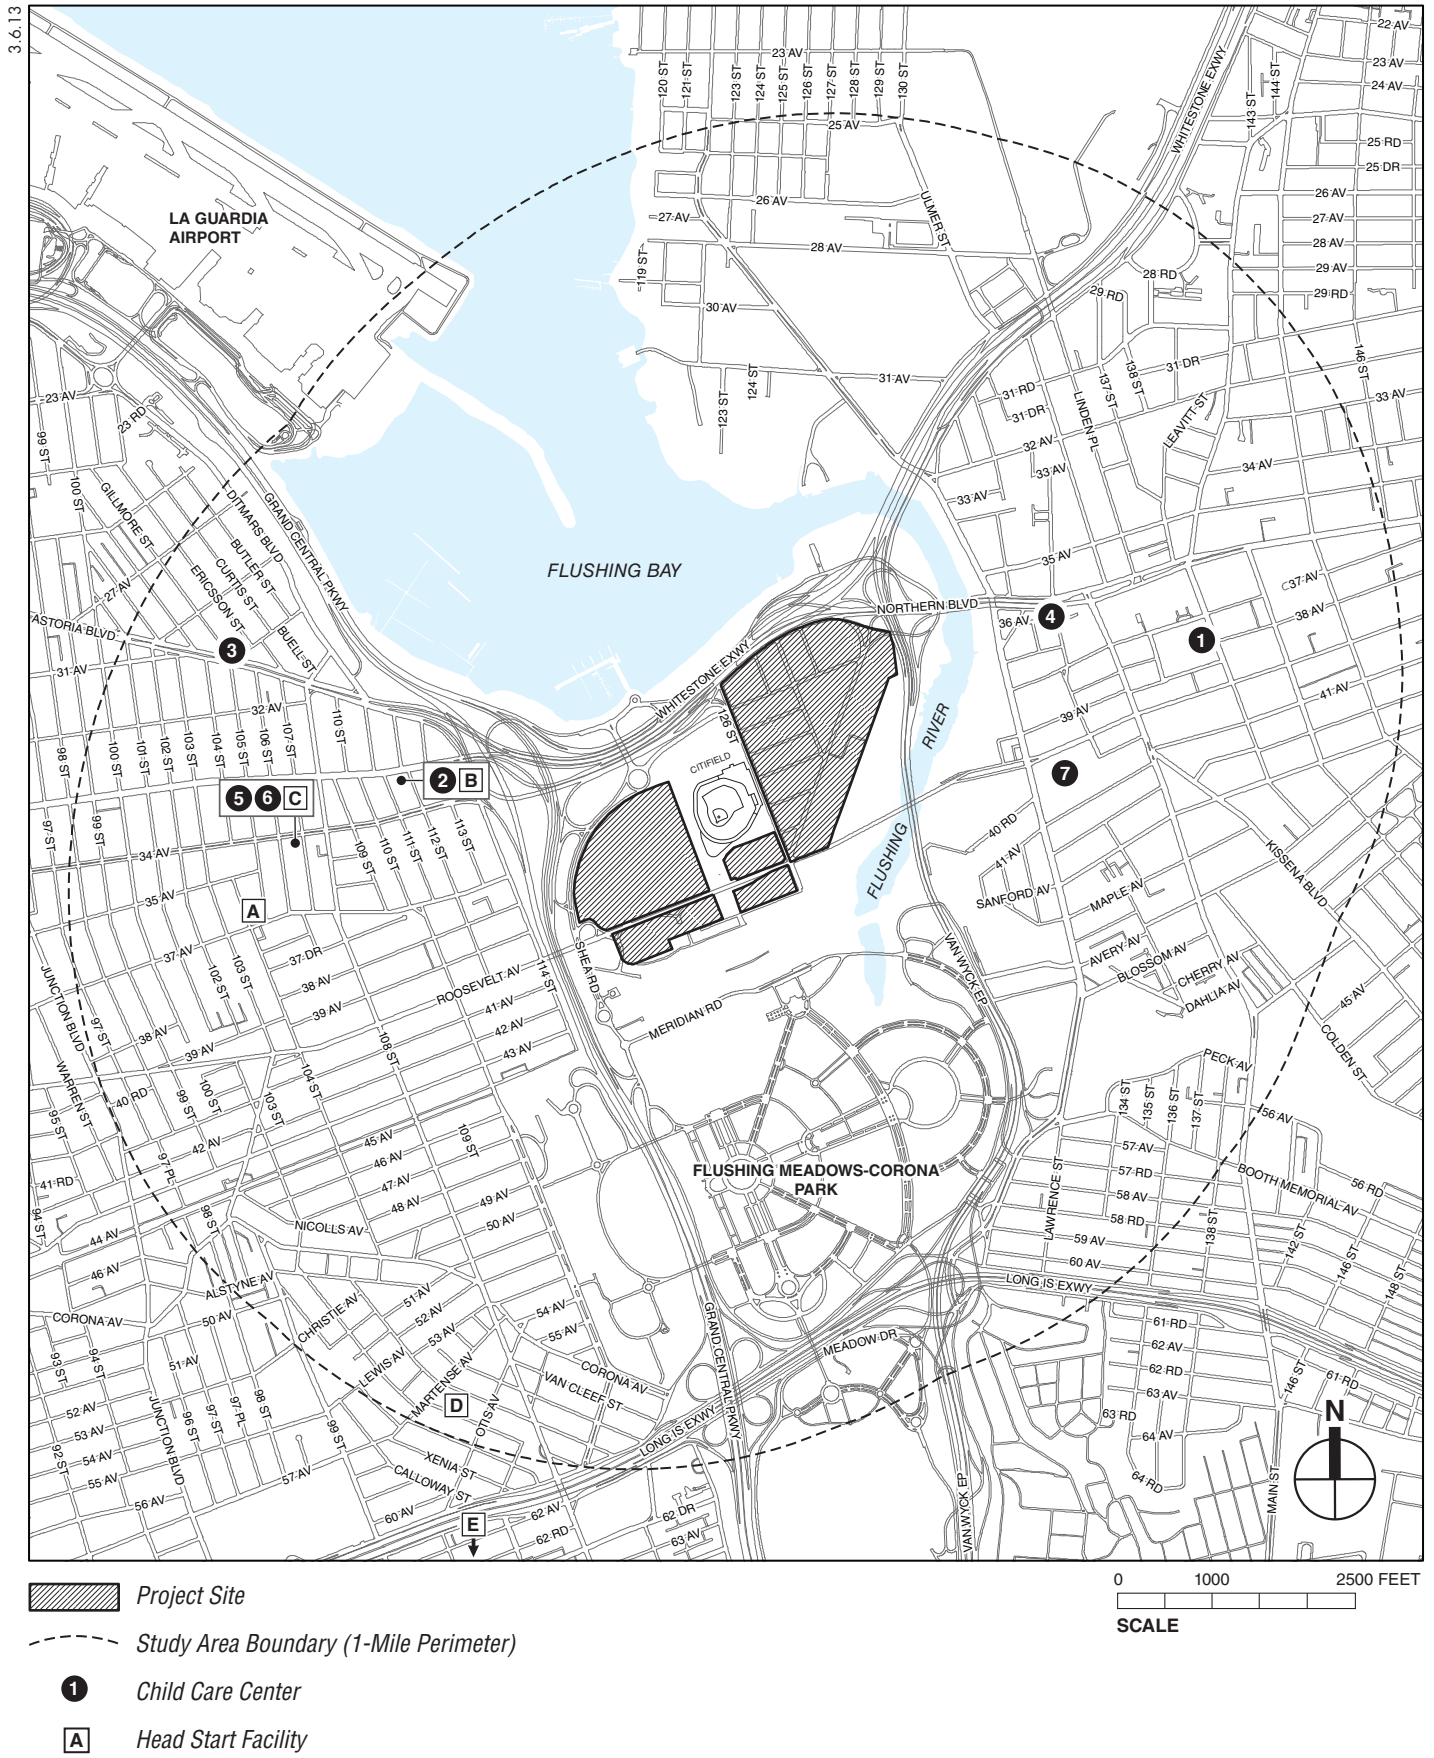

Table 4-12
Publicly Funded Child Care Facilities Serving the Study Area

Map ID	Name	Address	Enrollment	Capacity	Available Slots	Utilization Rate
Child Care						
1	Martin L. King, Jr. Memorial Day Care Center	36-06 Prince St	35	35	0	100%
2	Malcolm X Day Care Center	111-12 Northern Blvd	114	120	6	95%
3	Jerome Hardeman Sr. Child Care Center	29-49 Gillmore St	60	60	0	100%
4	Macedonia Child Development Center	37-22 Union St	35	35	0	100%
5	Better Community Life Day Care Center #1	34-10 108 St	74	80	6	93%
6	The Child Care Center of New York	34-10 108 St	55	58	3	95%
7	Better Community Life li Day Care Center	133-16 Roosevelt Ave	52	59	7	88%
	Child Care Total		425	447	22	95%
Head Start						
A	Catholic Charities	35-34 105 St	90	90	0	100%
B	The Child Center of New York	111-12 Northern Blvd	68	68	0	100%
C	The Child Center of New York	34-10 108th St	58	57	-1	102%
D	B'Above/International Children's Center	57-27 Penrod Street	102	102	0	100%
E	B'Above/Forest Park Nursery & Kindergarten	102-35 63rd Road	73	73	0	100%
	Head Start Total		391	390	-1	100%
	Grand Total		816	837	21	97%
Source: ACS, June 2012.						

Based on these assumptions, the number of available slots in the 2018 No Action condition would decrease, and utilization would increase to 107 percent, with a shortfall of 55 slots. No development projects or changes to the existing inventory of child care facilities are known to be planned in the study area after 2018. Therefore, the utilization rate for publicly funded child care facilities serving the study area is assumed to remain at 107 percent in the 2028 and 2032 No Action conditions.

PROBABLE IMPACTS OF THE PROPOSED PROJECT

PHASE 1A (2018)

The proposed project would not result in any new residential development by 2018; therefore, the child care facility utilization rate would remain the same as in the No Action condition (105 percent).

PHASE 1B (2028)

By 2028, Phase 1B of the proposed project would introduce a total of approximately 2,490 residential units, of which 872 units (35 percent) would be affordable. Based on the CEQR generation rates for the projection of children eligible for publicly funded child care, these new units would introduce approximately 122 new children under the age of six who would be eligible for publicly funded child care programs.

Willeys Point Development

As noted above, the *CEQR Technical Manual* guidelines indicate that a demand for slots greater than the remaining capacity of child care facilities and an increase in demand of 5 percent of the study area capacity could result in a significant adverse impact. With the addition of 122 children from the proposed development in the District, child care facilities in the study area would operate at 121 percent utilization, with a deficit of 177 slots. Total enrollment in the study area would increase to 1,014 children, compared with a capacity of 837 slots, which represents an increase in the utilization rate of 15 percentage points over the No Action condition.

Therefore, the proposed project could result in significant adverse impacts on publicly funded day care centers in the study area by 2028.

To mitigate this impact, QDG would consult with ACS to determine whether adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site is the appropriate way to meet demand for child care services generated by development on the project site by 2028. At this point, however, it is not possible to know exactly which type of mitigation would be most appropriate and when, because several factors may limit the number of children in need of publicly funded child care slots. Families in the study area could make use of alternatives to publicly funded child care facilities, such as homes licensed to provide family child care which families of eligible children could elect to use instead of a public child care center. As noted above, these facilities provide additional slots in the study area but are not included in the quantitative analysis. In addition, parents of eligible children may use ACS vouchers to finance care at private child care centers either within the study area or could use facilities outside of study area.

PHASE 2 (2032)

By 2032, the proposed project would introduce a total of approximately 5,850 residential units, of which 2,048 units (35 percent) would be affordable. Based on the CEQR generation rates for the projection of children eligible for publicly funded child care, these units would introduce approximately 287 new children under the age of six who would be eligible for publicly funded child care programs.

With the addition of 287 children from the proposed development in the District, child care facilities in the study area would operate at 141 percent utilization, with a deficit of 342 slots. Total enrollment in the study area would increase to 1,179 children, compared with a capacity of 837 slots, which represents an increase in the utilization rate of 34 percentage points over the No Action condition. Therefore, the proposed project could result in significant adverse impacts on publicly funded child care centers in the study area. Should this occur, the proposed project would require mitigation for the impact. Possible mitigation measures include adding capacity to existing facilities or providing a new child care facility within or near the area surrounding the project site. As discussed above, it is not possible to know exactly which type of mitigation would be most appropriate and when, because several factors may limit the number of children in need of publicly funded child care slots. Furthermore, as described in Chapter 1, "Project Description," a developer for Phase 2 has not yet been selected. QDG may or may not be selected as the designated developer for Phase 2. Therefore, consistent with the conclusions of the 2008 FGEIS, it is anticipated that to mitigate the potential impact on child care facilities that could occur by 2032, EDC would require, as part of the developer's agreement, that the designated developer of Phase 2 consult with ACS to determine the appropriate way to meet demand for child care services generated by development in the District by 2032.

G. HEALTH CARE FACILITIES

METHODOLOGY

The *CEQR Technical Manual* recommends detailed analyses of impacts on health care facilities in cases where a proposed action would affect the physical operations of, or direct access to and from, a hospital or a public health clinic, or where a proposed action would create a sizeable new neighborhood where none existed before. As stated above, the proposed project would not result in direct effects on any health care facility; however, the proposed project would result in the creation of a new neighborhood with residential uses where the demand for hospital and public health clinic services could increase with the addition of approximately 16,029 new residents as well as new workers and visitors. This section assesses the proposed project's potential impacts on health care facilities. The assessment identifies health care facilities within approximately one mile of the proposed project site.

EXISTING CONDITIONS

Health care facilities include public, proprietary, and non-profit facilities that accept public funds (usually in the form of Medicare and Medicaid reimbursements) and are available to any member of the community. Examples of these types of facilities include hospitals, nursing homes, clinics, and other facilities providing outpatient health services. The health care assessment focuses on emergency and outpatient ambulatory services that could be affected by the introduction of a large low-income residential population which may rely heavily on nearby hospital emergency rooms and other public outpatient ambulatory services.

HOSPITALS AND EMERGENCY ROOMS

There are no hospitals within a one-mile radius of the project site; however, the Flushing Hospital Medical Center and the New York Hospital Medical Center of Queens, both in Flushing, are located a few blocks from the one-mile study area boundary (see **Table 4-13** and **Figure 4-4**). As the *CEQR Technical Manual* guidelines do not specify a specific study area boundary, the Flushing Hospital Medical Center and the New York Hospital Medical Center of Queens were included in the analysis due to their proximity to the project site.

Table 4-13

Hospitals and Emergency Rooms within One Mile of Project Site

Hospital	Address	Outpatient Department Visits (2011)	Emergency Room Visits (2011)	Beds
Flushing Hospital Medical Center	4500 Parsons Boulevard	40,774	43,847	293
New York Hospital Medical Center of Queens	56-45 Main Street	141,264	121,466	519
Total		182,038	165,313	812
Sources: Flushing Hospital Medical Center 2012 Fact Sheet; New York Hospital Medical Center of Queens web site and Annual Report 2010-2011.				

The Flushing Hospital Medical Center is located at 4500 Parsons Boulevard. It provides a wide range of clinical services. According the hospital's 2012 Fact Sheet (posted on its web site), Flushing Hospital Medical Center had 293 beds, 40,744 outpatient department visits and 43,847 emergency room visits in 2011. As of 2011, the New York Hospital Medical Center of Queens,

-  Project Site
-  Study Area Boundary (1-Mile Perimeter)
-  Hospital
-  Outpatient Health Service Facility

NOTE: See Table 5-14 for reference

Health Care Facilities
Figure 4-4

Willels Point Development

located at 56-45 Main Street, had 519 beds, 141,264 outpatient visits, and 121,466 emergency room visits.

OTHER OUTPATIENT SERVICES

Table 4-14 and **Figure 4-4** show the inventory of the sixteen specific outpatient locations within one mile of the proposed project site (as inventoried in the *New York City Department of City Planning Selected Facilities and Program Sites in New York City, 2011 Edition*). These outpatient locations cover the entire area with a full range of ambulatory care facilities.

Table 4-14
Outpatient Health Care Facilities within the One-Mile Study Area

Map No.	Facility Name	Address	Facility Type
1	Cliffside Renal Dialysis	119-19 Graham Court	Health Center
2	Association for Neurologically Impaired Brain Injured Children, Inc.	30-56 Whitestone Expressway	Day Training
3	Rego Park ADHCP	145-18 34th Avenue	Adult Day Health Care Center
4	Flushing Manor Dialysis Center, LLC	36-17 Parsons Blvd	Health Center
5	Main Street Radiology at Bayside	136-25 37th Avenue	Health Center Extension Clinic
6	Asian Health Center of Flushing	136-26 37th Avenue	Health Center Extension Clinic
7	Chinese American Planning Council	136-26 37th Avenue	Senior Citizen/Geriatric Service
8	Family Health Center	13656 39th Avenue	Hospital Extension Clinic
9	Queens Child Guidance Center	41-25 Kissena Blvd	Clinic Treatment
10	Visiting Nurse Service of New York	41-61 Kissena Blvd	Clinic Treatment
11	The Child Center of NY – Flushing Clinic	140-15 Sanford Avenue	Day Treatment

13	Rego Park ADHCP	42-34 Saull Street	Adult Day Health Care Center
14	Elmcor Y/A Activities - Outpatient	107-20 Northern Blvd	Outpatient Clinic
15	Urban Health Plan Extension Clinic	37-12 108th Street	Health Center Extension Clinic
16	Corona Child Health Clinic	104-04 Corona Avenue	Hospital Extension Clinic
Note: Please refer to Figure 4-4 for location of outpatient facilities.			
Source: DCP, <i>Selected Facilities and Program Sites, 2011 Edition</i> .			

THE FUTURE WITHOUT THE PROPOSED PROJECT

There are no known capacity changes planned for the Flushing Hospital Medical Center or the New York Hospital Medical Center of Queens.

In the No Action condition, known planned or proposed development projects will introduce approximately 3,542 housing units, all of which are expected to be complete by 2018. In most cases, the projects that are planned or under construction in the study area are market-rate construction projects. However, for the purpose of this analysis, it is conservatively assumed that 20 percent of units in developments of 20 or more units within the one-mile study area will be occupied by low-to moderate-income residents (with the exception of Sky View Parc, which is being developed as luxury condominiums). Therefore, absent the proposed project, the low- to moderate-income population of the study area is expected to increase by 1,530 persons (543 new low- to moderate-income units multiplied by the average household size for Queens) as a result of the planned residential developments identified. All of this additional population will be added by 2018.

It is not expected that the increase in the study area population in the future without the proposed project will adversely affect the overall provision of health care services. Based on data from the U.S. Department of Health and Human Services, 30.6 percent of adults 18 years and over with incomes below poverty level had at least one emergency department visit in 2010, and 14.9 percent had two or more emergency department visits. For children living below poverty level, 13.4 percent had two or more emergency department visits in 2010.¹

Assuming the national averages cited above would apply to the new residents introduced to the study area in the No Action condition, and assuming two adults per household, approximately 332 of the new low- to moderate-income adults would have at least one emergency department visit, 162 would have at least two emergency department visits, and 60 children would have at least two emergency department visits per year. These incremental changes are small compared to the 165,313 emergency department visits experienced by Flushing Hospital Medical Center and New York Hospital Medical Center of Queens in 2011.

PROBABLE IMPACTS OF THE PROPOSED PROJECT

According to the *CEQR Technical Manual*, health service impacts can occur if a proposed project results in an increase of 5 percent or more in the demand for services compared with conditions in the future without the proposed project, or if a project results in a facility exceeding its capacity.

PHASE IA (2018)

The proposed project would not result in any new residential development by 2018, therefore the ability for Flushing Hospital Medical Center and New York Hospital Medical Center of Queens to serve the study area would remain the same as in the No Action condition.

PHASE IB (2028)

By 2028, Phase 1B of the proposed project would introduce approximately 2,490 residential units, of which 872 units (35 percent) would be affordable. These 872 units would introduce approximately 2,459 low-income persons to the study area by 2028 (872 affordable housing units multiplied by the average household size for Queens). Based on the national averages and household composition assumptions cited above under the Future Without the Proposed Project, the proposed project could introduce approximately 534 low- and moderate-income adults with one or more emergency department visits per year, approximately 260 adults with two or more emergency department visits per year, and approximately 96 children with two or more emergency department visits per year. It is not possible based on currently available statistics to develop a precise estimate for incremental project-generated emergency department visits. However, given the thousands of emergency department visits in the study area currently (165,313 in 2011), the additional affordable housing population would generate a minimal change in demand over the No Action condition. This increase would be less than the *CEQR Technical Manual's* general threshold of 5 percent and would not result in a significant adverse impact on hospitals and emergency rooms.

¹ National Center for Health Statistics. *Health, United States, 2011: With Special Feature on Socioeconomic Status and Health*. Hyattsville, MD. 2012. Tables 93 and 94.

PHASE 2 (2032)

By 2032, Phase 2 of the proposed project would introduce a total of approximately 5,850 residential units, of which 2,048 units (35 percent) would be affordable. These units would introduce a total of approximately 5,775 low-income persons to the study area by 2032 (2,048 units multiplied by the average household size for Queens). Based on annual statistics and household composition assumptions described above, the new population would introduce approximately 1,253 low- and moderate-income adults with one or more emergency department visits per year, approximately 610 adults with two or more emergency department visits per year, and approximately 225 children with two or more emergency department visits per year. This represents a minimal increase in demand over the No Action condition, and would be less than the *CEQR Technical Manual's* general 5 percent threshold. As with the proposed project in 2028, the proposed project at full build-out would not result in a significant adverse impact on hospitals and emergency rooms.

H. POLICE AND FIRE PROTECTION SERVICES

The *CEQR Technical Manual* recommends detailed analyses of impacts on police and fire service in cases where a proposed action would affect the physical operations of, or direct access to and from, a precinct house or fire station, or where a proposed action would create a sizeable new neighborhood where none existed before. As stated above, the proposed project would not result in these direct effects on either police or fire services; however, the proposed project would result in the creation of a new neighborhood with residential uses where the demand for police, fire, and emergency services could increase with the addition of approximately 16,029 new residents as well as new workers and visitors. This section assesses the proposed project's potential impacts on police, fire, and emergency medical services.

POLICE PROTECTION SERVICES

As shown in **Table 4-15** and **Figure 4-5**, the proposed project site is served by the 110th Precinct of the New York City Police Department (NYPD). The 110th Precinct is located at 94-41 43rd Avenue in Elmhurst. The District—the portion of the project site where the residential uses would be located—is also close to the 109th Precinct, located at 37-05 Union Street in Flushing.

Table 4-15
Police Protection Facilities

Map No.	Police Facility	Address	Communities Served
P1	109th Precinct	37-05 Union Street, Flushing	Downtown Flushing, East Flushing, Queensboro Hill, College Point, Malba, Whitestone, Beechhurst, Bay Terrace
P2	110th Precinct	94-41 43rd Avenue, Elmhurst	Elmhurst, Corona
Note: See Figure 4-5 .			
Source: Selected Facilities and Program Sites, NYC DCP.			

The 110th Precinct is located on 43rd Avenue in the Elmhurst neighborhood of Queens. The precinct serves an area bounded roughly by the Flushing River, the Long Island Expressway, 74th Street, and Roosevelt Avenue. As noted above, this precinct includes the District and also serves the communities of Corona and Elmhurst. Apart from the existing industrial uses in the

District, the precinct is mainly a residential/commercial community consisting of multiple dwelling buildings.

NYPD average response time to all crimes-in-progress calls have increased citywide from fiscal year (FY) 2007 to FY 2011. During this time, NYPD response time to all crimes-in-progress increased from 6.9 minutes in FY 2007 to 8.4 minutes in FY 2011, and response times to critical crimes-in-progress increased from 4.2 minutes in FY 2007 to 4.6 minutes in FY 2011.^{1, 2}

In the 110th Precinct, the average response time to all critical crimes-in-progress was 4.4 minutes in FY 2010 (the most recent year for which data for the 110th Precinct is available). This was equivalent to the citywide average response time to critical crimes in progress, also 4.4 minutes in FY 2010. During FY 2007 and 2008, response times to critical crimes-in-progress in the 110th Precinct were shorter than in 2010, 3.7 and 3.8 minutes for FY 2007 and FY 2008, respectively.³

The 109th Precinct is located on Union Street in downtown Flushing. The precinct's service area is bounded roughly by the Long Island Sound, Flushing Meadows-Corona Park, the Long Island Expressway, and Utopia Parkway. The precinct serves the neighborhoods of Downtown Flushing, East Flushing, Queensboro Hill, College Point, Malba, Whitestone, Beechhurst and Bay Terrace.

The 109th Precinct's average response time to critical crimes-in-progress was 4.6 minutes in FY 2010. This response time was comparable to the citywide average of 4.4 minutes but slightly higher than response times in the precinct from FY 2007 through FY 2008, which were 4.2 and 4.1 minutes, respectively.⁴

The proposed project would generate additional traffic on roads throughout the area, including the possible routes used by NYPD vehicles to access the project site. Traffic at certain intersections near the project site may result in slower access for NYPD vehicles. However, when responding to emergencies, NYPD vehicles are not bound by standard traffic controls or rules and are capable of adjusting to congestion encountered en route to their destinations and are therefore less affected than other vehicles by such congestion. In addition, NYPD vehicles have access to enhanced sirens and lights that enable them to safely navigate through congested areas. These vehicles would be able to access the project site as they do other areas throughout New York City, including the most congested areas of Downtown Flushing.

By 2018, the new worker and visitor populations introduced by the proposed project could increase the demand for police protection services. This demand would increase in 2028 and 2032 as additional worker and residential populations are introduced to the project site. Per ongoing practice, NYPD will continue to evaluate its staffing and resource needs over time

¹ Mayor's Management Report, FY 2011, NYPD, p. 133.

² Critical crimes in progress include crimes such as shots fired, robbery, and assault with a weapon. All crimes in progress data also includes response times for serious (such as larceny from a person, assault not involving a weapon, larceny of an auto) and non-critical crimes (those crimes not involving an imminent threat of personal injury).

³ My Neighborhood Statistics web page at NYC.gov (<http://gis.nyc.gov/ops/mmr/address.jsp?app=MMR>). Response time data for critical crimes in progress in Precinct 110 in FY 2009 is not available.

⁴ My Neighborhood Statistics web page at NYC.gov (<http://gis.nyc.gov/ops/mmr/address.jsp?app=MMR>). Response time data for critical crimes in progress in Precinct 109 in FY 2009 is not available.

based on a variety of factors, including projected population increases and demographic shifts. Because the NYPD would continue to reevaluate its staffing and resource needs and would continue to have the ability to adjust to congestion en route to emergencies, response times are not expected to dramatically change in such a way as to result in a significant adverse impact. Therefore, the proposed project would not result in any significant adverse impacts to police protection in 2018, 2028, or 2032 that were not addressed in the 2008 FGEIS.

FIRE PROTECTION SERVICES

At structural fires citywide, New York City Fire Department (FDNY) engine companies perform fire suppression efforts, while ladder companies provide search, rescue, and building ventilation functions. Rescue and squad companies specifically respond to fires or emergencies in support of the other units and can perform any specialized tasks or functions as necessary. In addition, FDNY operates the City's emergency medical services (EMS) system.

Units responding to a fire are not limited to ones closest to it. Normally, a total of three engine companies and two ladder companies respond to each call. Each FDNY squad company is capable of operating as an engine, ladder, or technical rescue company, making them versatile for incident commanders. Each squad is also part of the FDNY HazMat Response Group and has HazMat Tech Unit capabilities. FDNY can call on units in other parts of the City as needed.

Table 4-16 lists the fire companies that may be called on to respond to a fire or other emergency at the project site (see **Figure 4-5**). Engine Company 273/Ladder Company 129 on Union Street in Flushing are the units located closest to the District, with Engine Company 289/Ladder Company 138 on 43rd Avenue in Corona second closest. The other FDNY facilities listed are also in a position to respond promptly to the project and provide response capabilities from every direction. In the area surrounding the project site, the FDNY is experienced with the logistical issues of providing support for single and simultaneous events occurring at CitiField, Flushing-Meadows Corona Park, and the USTA National Tennis Center.

Table 4-16
Fire Protection Facilities

Map No.	Fire Facility	Address	Facility Type
F1	Engine 273 Ladder 129	40-18 Union Street	Fire House
F2	Engine 289 Ladder 138	97-28 43rd Avenue	Fire House
F3	Engine 297 Ladder 130	119-11 14th Road	Fire House
F4	Engine 316	27-12 Kearney Street	Fire House
F5	Engine 324 Satellite 4 Division	108-01 Horace Harding Expressway	Fire House
Note: See Figure 4-5 .			
Sources: Selected Facilities and Program Sites, DCP.			

In 2011, the average response time to structural fires for all fires was 4 minutes 23 seconds in Queens, compared to 4 minutes 3 seconds citywide. These response times represent a modest increase compared to 2010, when the average structural fire response times in Queens and citywide were 4 minutes 20 seconds and 3 minutes 59 seconds, respectively.¹

There are two types of ambulances in the City—911 providers and those providing inter-facility transport. Municipal FDNY and hospital-based ambulances are the sole providers of 911 services, and they operate that system under contract with FDNY. (Inter-facility transports are carried out

¹ New York City Mayor's Management Report.

by private contractors and do not participate in the 911 system.) All hospital-based ambulances which operate in the New York City 911 System do so by contractual agreement with FDNY's EMS Command. All ambulances in the 911 system are dispatched by FDNY under the same computer-based system, regardless of hospital affiliation. All EMS units are assigned a permanent cross-street location where they await a service call; units return to this location once service is complete. These locations are determined by FDNY and based on historical call volumes by location and time of day. In addition to FDNY ambulances, the project site is served by ambulances operated by Flushing Hospital and the New York Hospital of Queens.

Medical response times increased in FY 2011 compared to FY 2010, with the citywide response time to life-threatening medical emergencies by fire units increasing by 3 seconds from 4 minutes and 17 seconds to 4 minutes and 20 seconds and the response by ambulance units increasing by 19 seconds from 6 minutes and 41 seconds in FY 2010 to 7 minutes in 2011. According to the New York City Mayor's Management Report, this increase is primarily due to the two-day blizzard in December 2010 and its aftermath. Between FY 2007 and FY 2010, the combined response time to life-threatening medical emergencies by fire units and ambulance units citywide remained more constant, increasing by 4 seconds.¹

The new residential, worker, and visitor populations introduced by the proposed project could increase the demand for FDNY and EMS services. Fire protection throughout the city is normally provided by multiple fire companies and fire protection in the study area will continue to be provided as per established standard FDNY operating procedures.

The proposed development would meet all relevant New York City fire safety standards. In addition, the proposed project includes significant infrastructure improvements for the District, including road grading and paving, as well as improvements to City water service, including fire hydrants. As such, the proposed project would result in significant improvements to on-site infrastructure that would bolster FDNY's firefighting ability within the District portion of the project site.

The proposed project would generate additional traffic on roads throughout the area, including the possible routes used by FDNY and EMS vehicles to access the project site. Traffic at certain intersections near the project site may result in slower access for FDNY and EMS vehicles. However, FDNY and EMS vehicles, when responding to emergencies, are not bound by standard traffic controls or rules and are capable of adjusting to congestion encountered en route to their destinations and are therefore less affected than other vehicles by such congestion. FDNY vehicles are also equipped with enhanced sirens and emergency lights that assist them in safely navigating through congested areas. These vehicles would be able to access the project site as they do other areas throughout New York City, including the most congested areas of Downtown Flushing.

As noted above, EMS units are assigned a permanent cross-street location where they await a service call. If warranted by demand, the FDNY could assign an EMS unit within the District to provide services to the new population.

Overall, the proposed project would not result in any significant adverse impacts to fire protection or emergency services in 2018, 2028, or 2032 that were not addressed in the FGEIS and subsequent technical memoranda. *

¹ NYC Mayor's Management Report, p 144.

A. INTRODUCTION

This chapter assesses the potential of the proposed project to affect open space resources. The analysis updates changes to the proposed project and background conditions since the 2008 Final Generic Environmental Impact Statement (FGEIS) and assesses whether any changed background conditions or the differences between the reasonable worst-case development scenario (RWCDS) and the program assessed in the 2008 FGEIS and subsequent technical memoranda would result in any significant adverse impacts on open space that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

This analysis finds that the RWCDS would not result in significant adverse open space impacts that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

DIRECT EFFECTS

By 2018, the Willets West portion of the proposed project would be constructed upon 30.7 acres of the surface parking lot west of CitiField, and one the CitiField parking lots along Roosevelt Avenue (South Lot) would also be developed. While this land is mapped as parkland, it does not function as recreational open space. The land was occupied by Shea Stadium and associated parking and circulation space until it was replaced by CitiField in 2009, and it is now occupied exclusively by surface parking. There is one event—the Major League Wheelchair Softball Tournament—that is held in this area; however, this is not an event that provides open space on a constant and regular basis for designated daily periods. This use is therefore not considered a public open space use as defined under City Environmental Quality Review (CEQR). Furthermore, the Major League Wheelchair Softball Tournament would be relocated to the Special Willets Point District in Phase 1A of the proposed project. Therefore, developing this mapped parkland has no direct effect on the adequacy of open space for the study area residential and non-residential populations.

The proposed project would activate the Willets West area, making the area more appealing to residential and non-residential populations and improving connections between the study area populations and the Flushing Bay Promenade. It is anticipated that some of the trees within the Willets West portion of the project site would require removal during construction, as would trees within the Lot B area. Tree removal and replacement would be conducted in conformance with New York City Department of Parks and Recreation (DPR) requirements, including approval from DPR's Queens forestry division. The portions of the project to be constructed by 2028 and 2032 also would have no direct effect on the adequacy of open space for the study area residential and non-residential populations.

The proposed project would not have any adverse impacts on existing open space in terms of air quality, noise, or shadows (see Chapter 6, “Shadows,” Chapter 15, “Air Quality,” and Chapter 17, “Noise” for additional information). The World’s Fair Marina Park, which was predicted in the 2008 FGEIS to experience a significant adverse noise impact during the Saturday midday time period, is no longer expected to experience a significant adverse impact.

The proposed project would add to the inventory of open space in the study area. During Phase 1A of the proposed project, the parking area within the Special Willets Point District would be converted to active recreational use a minimum of six months per year. Permanent publicly accessible open space would be built as part of Phase 1B and Phase 2, in accordance with the District’s zoning requirements as residential populations are introduced. Phase 1B would include approximately six acres of new publicly accessible open space, approximately 3.5 of which would subsequently be developed with new structures in Phase 2. Phase 2 would create another 5.5 acres of open space, for a total of 8 acres of publicly accessible open space at the conclusion of the development of the proposed project.

INDIRECT EFFECTS

Although the development of the proposed project would include the creation of publicly accessible open space, because it would also introduce demand from a new population the RWCDs would result in a decrease in total, active, and passive open space ratios in the residential study area and a decrease in total and passive open space ratios in the non-residential study area. These decreases would not result in a significant adverse open space impact. Open space ratios would remain near or above the recommended City guidelines, with the exception of the active open space ratio, which would decrease from 1.80 acres per 1,000 residents in the 2018 No Action condition to 1.54 in the 2028 With Action condition and 1.31 in the 2032 With Action condition. The total open space ratio would remain above the recommended City guideline until 2032, when it would decrease to 2.46, falling slightly below the guideline of 2.5 acres per 1,000 residents. The amount of active open space available in the study area during Phase 1A would be higher than indicated by the ratios, due to the presence of the interim active recreational use to be provided within the District, which was not considered in the open space ratios. Upon completion, the RWCDs would include a minimum of 8 acres of publicly accessible open space, including an approximately two-acre park developed with primarily active recreational uses.

The RWCDs would not result in a significant adverse open space impact during any of the three analysis years. The proposed project would introduce substantial new open space, and study area residents would continue to have access to the portions of Flushing Meadows-Corona Park and the Flushing Bay Promenade that fall just outside of the residential study area’s boundaries. Further, Queens Development Group, LLC (QDG) would work to incorporate ground-level, active open space and other recreational resources such as rooftop and interior programming of recreational amenities into the project design for Phase 1B, and the New York City Economic Development Corporation (EDC) would encourage through its formal RFP process the future developer of Phase 2 to incorporate similar features into the Phase 2 development. While these recreational amenities may be available only to tenants and residents of the site—and thus have not been included in the quantitative analysis—these amenities would help offset the burden on public active and passive resources resulting from the introduction of new users on the project site.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS and subsequent technical memoranda analyzed the potential for impacts on open space resulting from the development of the Willets Point Development Plan and the No Convention Center Scenario, as well as the potential development of Lots B and D. The 2008 FGEIS assessed potential impacts on open space within a ¼-mile radius of the Special Willets Point District for passive open space and a ½-mile radius for active open space.

The 2008 FGEIS and subsequent technical memoranda concluded that in the future with the proposed Plan, the area surrounding the District would continue to have adequate active and passive open space resources. Open space ratios would continue to be well above City guidelines, except for the active open space ratio per 1,000 residents and the passive open space ratio per 1,000 workers, which would be below the recommended ratios. The open space ratios indicated that workers and residents would continue to have adequate open space to meet their needs in the future with the proposed Plan or the No Convention Center Scenario. Furthermore, the 2008 FGEIS noted that these quantitative analyses did not consider the extensive open space resources just beyond the study area boundaries, particularly the numerous active recreational amenities in the remaining portions of Flushing Meadows-Corona Park. The 2008 FGEIS concluded that neither the proposed Plan nor the No Convention Center Scenario, nor the potential development of Lots B and D, would be expected to result in significant adverse impacts on study area open spaces.

C. METHODOLOGY

This chapter examines the potential impacts on open space resources from the RWCDs in accordance with the guidelines of the 2012 *CEQR Technical Manual*. The chapter examines potential direct effects of the RWCDs on nearby publicly accessible open spaces (e.g., addition or reduction in open space, shadows, noise increases) as well as indirect effects created by changes in demand for and use of the area's open spaces. The analysis inventories the conditions and use of open spaces within a ¼-mile radius of the project site for passive open space and a ½-mile radius of the project site for active open space and addresses impacts on these facilities both qualitatively and quantitatively.

ANALYSIS APPROACH

As discussed in Chapter 1, “Project Description,” the analyses in this Supplemental EIS (SEIS) compare conditions in the future without the proposed project (No Action condition) to conditions in the future with the proposed project (With Action condition). The No Action condition in all technical areas assumes that none of the discretionary actions now being sought by QDG are approved. Absent those approvals, it is assumed for the purposes of a conservative analysis that in each No Action scenario, no change would be made to any portion of the project site, and the existing uses on the project site would be maintained.

DIRECT EFFECTS ANALYSIS

According to the *CEQR Technical Manual*, a proposed project would directly affect open space conditions if it causes the loss of public open space, changes the use of an open space so that it no longer serves the same user population, limits public access to an open space, or results in increased noise or air pollutant emissions, odors, or shadows that would temporarily or

permanently affect the usefulness of a public open space. This chapter uses information from Chapter 6, “Shadows,” Chapter 15, “Air Quality,” and Chapter 17, “Noise,” to determine whether the RWCDS would directly affect any open spaces near the project site. A proposed project can also directly affect an open space by enhancing its design or increasing its accessibility to the public. The direct effects analysis is included below in “Probable Impacts of the Proposed Project.”

INDIRECT EFFECTS ANALYSIS

As described in the *CEQR Technical Manual*, open space can be indirectly affected by a proposed action if the project would add enough population, either residents or non-residents, to noticeably diminish the capacity of open space in an area to serve the future population. Typically, an assessment of indirect effects is conducted when a project would introduce 200 or more residents or 500 or more workers to an area; however, the thresholds for assessment are slightly different for areas of the City that have been identified as either underserved or well served by open space. Because the project site is not located within an area that has been identified as either underserved or well served, the 200 resident and 500 worker thresholds were applied in this analysis.

At full build out (Phase 2), the proposed project would introduce approximately 5,850 new residential units, with an estimated residential population of 16,029, and 9,666 workers. An additional 1,581 workers would be added by the potential development of Lot B by 2032. Because the RWCDS would generate more than 200 residents and 500 workers, an open space assessment is warranted.

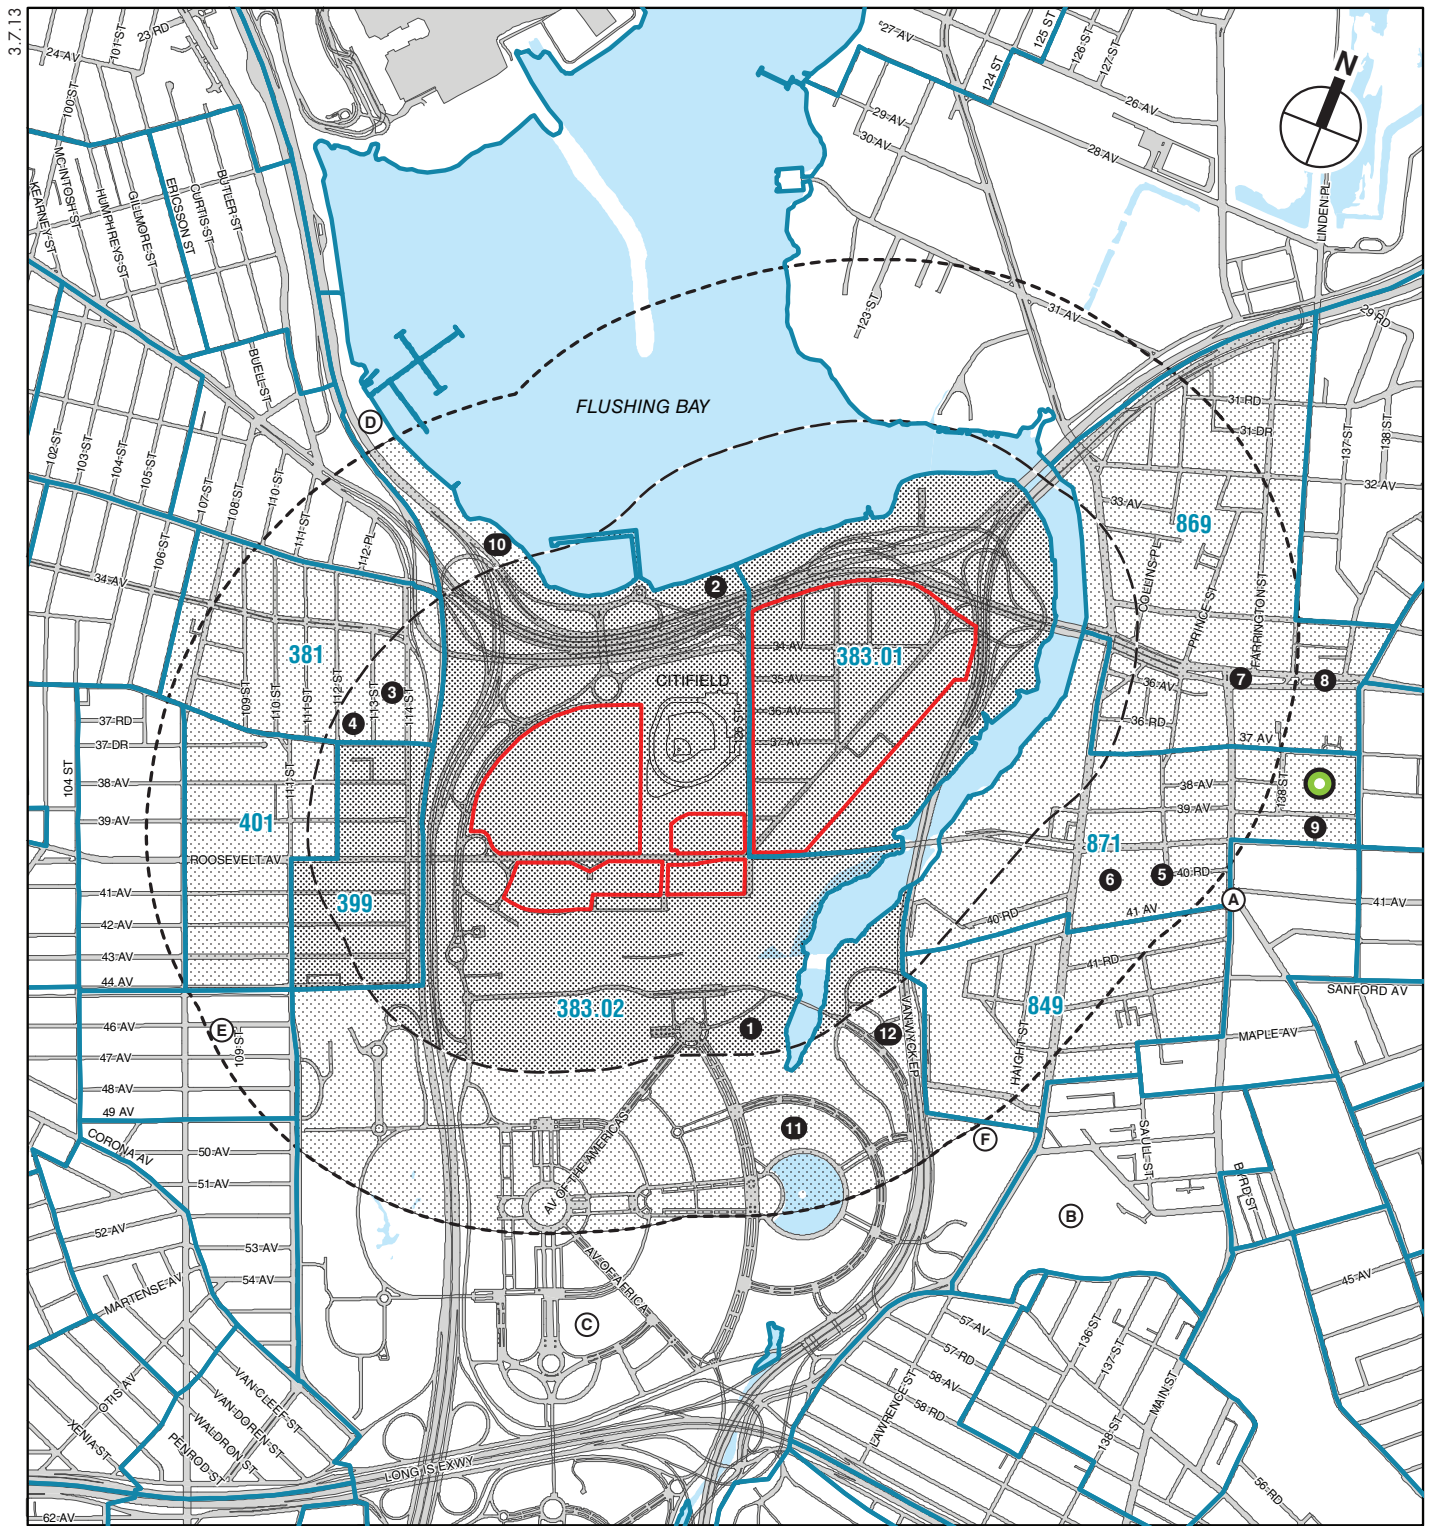

The *CEQR Technical Manual* suggests that a detailed open space analysis is necessary if a project displaces a highly utilized open space or introduces a large population in an area with low existing open space ratios. While the proposed project is located in an area with open space ratios that are currently above the City’s planning goals, a preliminary analysis indicated that the project would result in a decrease in open space ratios of substantially over 5 percent due to the sizable residential and non-residential populations that would be introduced by the project. Therefore, a detailed open space analysis was conducted, as described below.

STUDY AREAS

The *CEQR Technical Manual* recommends establishing a study area or areas as the first step in an open space assessment. The study areas are based on the distance that the respective users—residents and workers—are likely to walk to an open space. According to the *CEQR Technical Manual*, workers are assumed to walk approximately 10 minutes, or ¼ mile from their place of work to an open space, while residents are assumed to walk approximately 20 minutes, or ½ mile to an open space.

Because the RWCDS would introduce new residential and worker populations to the area, the adequacy of open space resources was assessed for both the ¼-mile (non-residential) and ½-mile (residential) study areas. These two study areas were adjusted to include all census tracts with at least 50 percent of their area within the ¼- or ½-mile boundary. In this way, the study area allows analysis of both the open spaces in the area as well as population data.

As shown in **Figure 5-1**, the ¼-mile non-residential study area is generally bounded by Flushing Bay to the north; the Van Wyck Expressway to the east; the USTA National Tennis Center (NTC) in Flushing Meadows-Corona Park to the south; and between 11th Street and the Grand Central Parkway to the west. The non-residential study area includes census tracts 383.01,

- | | |
|---|---|
| — Project Site Boundary | — Census Tract Boundary |
| - - - 1/4-Mile Study Area Boundary | 383.02 Census Tract Number |
| - - - 1/2-Mile Study Area Boundary | ❶ Open Space within Study Area (see Table 5-4) |
| 1/4-Mile Open Space Study Area (Commercial Study Area) | Ⓐ Open Space outside Study Area (see Table 5-4) |
| 1/2-Mile Open Space Study Area (Residential Study Area) | 🟢 Planned Flushing Commons Project (1.52 Acres of Open Space) |

0 1000 2000 FEET
SCALE

383.02, and 399. While the portion of census tract 383.02 that falls within the non-residential study area covers less than 50 percent of the census tract, the tract was included in the study area because it includes Willets West and those portions of the project site that are south of Roosevelt Avenue. Census tract 383.02 covers all of Flushing Meadows-Corona Park as well as a strip of land that runs along the Grand Central Parkway and Ditmars Boulevard toward LaGuardia Airport. To ensure a conservative quantitative analysis, only the portions of the open spaces within a ¼-mile radius of the District were included, but the tract's entire worker and resident populations were included.

The residential study area is generally bounded by Flushing Bay and the Van Wyck Expressway to the north; Linden Place, Union Street, and Main Street to the east; Flushing Meadows-Corona Park to the south; and 108th and 11th Streets to the west. The residential study area includes all the census tracts identified within the non-residential study area as well as census tracts 381, 401, 849, 869, and 871. While the boundaries of census tract 383.02 cover the entire Flushing Meadows-Corona Park and extend from Northern Boulevard to the Van Wyck Expressway, to ensure a conservative analysis the residential study area includes only the open space acreage within the park that falls within a ½-mile radius of the project site. As such, the residential study area's southern boundary is located north of Perimeter Road within Flushing Meadows-Corona Park and does not extend to the southern edge of tract 383.02. Although the analysis includes only the open spaces within a ½-mile radius of the project site, the quantitative analysis conservatively includes the tract's entire worker and resident populations.

STUDY AREA POPULATIONS

EXISTING CONDITIONS

The residential population in the study areas was estimated using 2010 Census data. The non-residential worker population was estimated using 2012 employment data from ESRI, Inc., a commercial data provider.

THE FUTURE WITHOUT THE PROPOSED PROJECT

As described in detail in Chapter 2, "Land Use, Zoning, and Public Policy," there are several developments expected to be completed in the ¼- and ½-mile study areas by 2032 in the No Action condition. The residential population in the No Action condition was estimated by applying the average household size for Queens (2.82 as of the 2010 Census) to the number of dwelling units added by the expected developments in the study areas. The number of workers added in the No Action condition was estimated using standard employment density ratios.

THE FUTURE WITH THE PROPOSED PROJECT

The population introduced by the RWCDS was estimated by applying the average household size for Queens (2.82) to the number of dwelling units that would be introduced by the RWCDS. The number of workers introduced by the RWCDS was estimated using standard employment density ratios.

INVENTORY OF OPEN SPACE RESOURCES

The *CEQR Technical Manual* defines public open space as open space that is publicly or privately owned and is accessible to the public on a regular basis, either constantly or for designated daily periods of time. Open spaces that are only available for limited users or are not

available to the public on a regular or constant basis are not considered public open space, but are considered in a qualitative assessment of open space impacts.

All publicly accessible open space resources in the non-residential and residential study areas were inventoried through field visits conducted in August 2012. Additional data were obtained from DPR, and other available sources.

Information was gathered about the types of facilities, levels of utilization, accessibility, and condition of each of the open space resources. According to CEQR guidelines, open spaces were also described in terms of the amount of active and passive facilities present. Active open space is used for exercise, sports, or active play, and is usually part of a recreational facility. Examples of active open space include playground equipment, athletic fields or courts, pools, and greenways. Passive open spaces encourage activities such as strolling, reading, sunbathing, people watching, and other forms of relaxation. Examples of passive open space include plazas, paths, gardens, and certain lawns with restricted uses. Open space may be characterized as passive, active, or a mixture of active and passive. Esplanades are an example of open space that may be used for active uses like running or passive dog walking.

In addition to the open spaces located in the study areas, open spaces located just outside of the study areas were considered in the qualitative analysis as they may be used by the worker or resident populations.

New open space that would be created in the No Action and With Action conditions was accounted for in the analysis.

ADEQUACY OF OPEN SPACE RESOURCES

COMPARISON TO CITY GUIDELINES

The adequacy of open space in the study area was quantitatively and qualitatively assessed for existing conditions, the future No Action condition, and the With Action condition. According to CEQR guidelines, the quantitative assessment is based on ratios of usable open space acreage to the study area populations (the “open space ratios”). These ratios were then compared with the City’s open space guidelines for residential and non-residential populations. The following guidelines are used in this type of analysis:

- For non-residential populations, 0.15 acres of passive open space per 1,000 non-residents is typically considered adequate.
- For residential populations, there is a Citywide median open space ratio of 1.5 acres per 1,000 residents, which is used as a guideline. In addition to this median ratio, the City has set an open space ratio planning goal of 2.5 acres per 1,000 residents. This second ratio includes 0.50 acres of passive space and 2.0 acres of active space, and serves as an ideal benchmark.

Because these ratios may not be attainable for all areas of the City, they are considered benchmarks for comparison rather than policy or thresholds for determining impacts.

IMPACT ASSESSMENT

Impacts are based on how a project would change the open space ratios in the study area. According to the *CEQR Technical Manual*, a project may result in significant adverse impacts to open space if there would be direct displacement or alteration of an open space that would

significantly impact the existing users; or, if the project would reduce open space ratios by more than 5 percent in an area that is currently below the City's median open space ratio. In areas that are extremely lacking in open space, a reduction as small as 1 percent may be considered significant, depending on the area of the City. In areas that are well served by open space, a greater change in the open space ratio may be tolerated.

The *CEQR Technical Manual* recommends that the quantitative open space analysis described above be supplemented by an examination of qualitative factors, as the significance of any changes to open space depends on the context of the proposed action, including the location, quality and quantity of open space in the With Action condition. These qualitative considerations include the availability of nearby destination resources, the connectivity of open space, the effects of new open space provided by the project, and the comparison of projected open space ratios with established City guidelines. It is recognized that the open space ratios of the City guidelines described above are not feasible for many areas of the City, and they are not considered impact thresholds on their own. Rather, they are benchmarks that indicate how well an area is served by open space.

D. EXISTING CONDITIONS

STUDY AREA POPULATION

Based on 2011 employment data obtained from ESRI, Inc. and District employment information provided by EDC, the non-residential study area has a worker population of 4,406 people (See Table 5-1).

Table 5-1
2012 Population in the 1/4-Mile Non-Residential Study Area

Census Tract	Worker Population
383.01	1,353
383.02	2,739
399	314
Total	4,406
Sources: Worker population for Tract 383.01, which encompasses the District, obtained from EDC. Worker population for remaining tracts obtained from ESRI Business Analyst Inc, Business Summary Report.	

Based on 2010 Census data, the residential study area has a population of 30,048 residents (see Table 5-2).

Table 5-2
2010 Population in the 1/2-Mile Residential Study Area

Census Tract	Residential Population

849	7,642
869	2,131
871	1,752
Total	30,048
Source: U.S. Census 2010	

AGE DISTRIBUTION

The age distribution of a residential population has open space implications in terms of the types of facilities that are in highest demand and how open spaces are used. As described in the *CEQR Technical Manual*, children 4 years or younger typically use traditional playgrounds with play equipment for toddlers and preschool children. Children ages 5 through 9 tend to use traditional playgrounds with play equipment suitable for school-age children, as well as open spaces with grass or hard surfaces for active play. Children ages 10 through 14 also tend to use playground equipment, as well as courts and ball fields. Teenagers and young adults between the ages of 15 and 19 typically use courts and active fields. Adults use facilities for sports and active fields as well as individualized recreation that utilizes paths. Senior citizens tend to utilize facilities for active recreation like handball, tennis, and swimming, as well as passive recreational facilities.

Table 5-3 summarizes the residential age distributions in the study areas and compares them with the distributions in Queens and New York City.

Table 5-3
Residential Population Age Distribution

Age Category	Residential (½-Mile) Study Area		Queens		New York City	
	Persons	Percent	Persons	Percent	Persons	Percent
4 and younger	2,318	7.7	132,464	5.9	517,724	6.3
5 to 9	1,892	6.3	123,766	5.5	473,159	5.8
10 to 14	1,525	5.1	123,406	5.5	468,154	5.7
15 to 19	1,855	6.2	139,096	6.2	535,833	6.6
20 to 64	20,446	68.0	1,425,844	63.9	5,187,105	63.45
65 and over	2,012	6.7	286,146	12.8	993,158	12.1
Total	30,048	100.0	2,230,722	100.0	8,175,133	100.0

Source: U.S. Census 2010.

As compared with Queens and New York City as a whole, the residential study area has a higher proportion of young children (ages 4 and younger, and 5 to 9) and working age population (ages 20 to 64). The residential study area has a lower proportion of senior residents (6.7 percent) compared to Queens (12.8 percent) and New York City (12.1 percent).

STUDY AREA OPEN SPACES

NON-RESIDENTIAL (¼-MILE) STUDY AREA

Portions of two open spaces, Flushing Meadows-Corona Park and the Flushing Bay Promenade, fall within the non-residential study area (see **Figure 5-1** and **Table 5-4**). For the purposes of a conservative analysis, only the publicly accessible portions of each park within the non-residential study area were included in the analysis. The analysis of the non-residential study area's open spaces did not include CitiField and its associated parking areas as open space resources because this land does not meet the *CEQR Technical Manual* definition for publicly accessible open space. While Hinton Park and Louis Armstrong Playground also fall within a ¼-mile of the proposed project site, they are not located in a census tract with at least 50 percent of its area in the ¼-mile radius, and therefore were included in the residential study area rather than the non-residential study area.

Table 5-4
Open Space Inventory

Map Number	Name	Owner	Features	Size (acres)	Acres of Active Open Space	Acres of Passive Open Space	Condition/ Utilization
Non-Residential Study Area							
1	Flushing Meadows-Corona Park	DPR	Benches, paved walkway, tennis courts, golf course	15.46	7.73	7.73	Fair/ Heavy
2	Flushing Bay Promenade	DPR	Benches, paved walkway	6.65	3.33	3.33	Good/ Moderate

Notes: See Figure 5-1 for location of open spaces. The open space inventory presented in the 2008 FGEIS included 1.74 acres of open space associated with the New York City Housing Authority's James A. Bland Houses and 0.42 acres of open space at Flushing Greens. These two open spaces were excluded from the SEIS analysis per direction from the NYC Department of Parks and Recreation.							
Sources: New York City Department of Parks and Recreation open space database; AKRF, Inc. field surveys, August 2012.							

Willeys Point Development

At 898 acres, Flushing Meadows-Corona Park is Queens' largest park and one of the largest in New York City. The non-residential study area covers a small portion of the park that falls within ¼ mile of the District and is publicly accessible. As a result, 15.46 acres of open space within Flushing Meadows-Corona Park were included in the analysis. Given the significant size of Flushing Meadows-Corona Park, the precise breakdown of active versus passive open space is unknown. This analysis assumes that approximately half of Flushing Meadows-Corona Park is for active recreation and half is dedicated to passive recreation. Therefore, in the non-residential study area, approximately 7.73 acres is assumed to be active open space, and the remaining 7.73 acres is for passive open space uses. As described above, CitiField and its associated parking areas are not included in the Flushing Meadows-Corona Park acreage for this analysis.

The Flushing Bay Promenade is a 1.4-mile greenway that runs along Flushing Bay from LaGuardia Airport to Flushing Meadows-Corona Park. The promenade was built in 2001 and includes an asphalt biking and walking path, benches, and lighting. Shea Road and Northern Boulevard provide access to the promenade, but the Grand Central Parkway and Northern Boulevard largely isolate the promenade from adjacent residential uses. The portion of the promenade within the non-residential study area includes a biking/walking path and seating, as well as the World's Fair Marina. The World's Fair Marina is a commercial marina facility and, therefore, was not included in the quantitative analysis. As a result, 6.65 acres of the promenade, half of which is considered active space and half of which is considered passive open space, are included in the non-residential study area.

Overall, the non-residential study area includes 22.11 acres of open space, with 11.06 acres of active open space and 11.06 acres of passive use.

RESIDENTIAL (½-MILE) STUDY AREA

The residential study area has eight public open spaces, which total 137.91 acres. Of this total, approximately 73.53 acres are active space and 64.39 acres are passive. Portions of Flushing Meadows-Corona Park and the Flushing Bay Promenade fall within the residential study area. These areas include the USTA National Tennis Center, which is open to the public free of charge for 11 months out of the year and offers below-market court rentals to the public, as well soccer fields, a portion of the pitch and putt golf course, and a large field for passive and active uses. In addition to these resources, the Flushing Meadows-Corona Park Aquatic Center is located within ½-mile study area. This recreational resource includes a public Olympic-sized indoor pool, which operates as a standard DPR recreation facility, and an NHL-standard indoor ice hockey rink. The pool is open to any member of the general public with a standard annual membership at all times except during swimming meets and other special events. The facility is free for youths under 18. The ice rink is open daily to any member of the general public for a \$5 admission fee on weekdays and an \$8 admission fee on weekends.

Other open space resources in the residential study area that are under DPR jurisdiction include Hinton Park, Louis Armstrong Playground, Bland Playground, the Daniel Carter Beard Mall, and additional portions of the Flushing Bay Promenade. Hinton Park is a 3.73-acre park that includes game tables and sitting areas, baseball diamonds, and other play areas. The Louis Armstrong Playground is a 1.9-acre park that includes a basketball court and play areas. The Bland Playground is located on the same block as the New York City Housing Authority (NYCHA)'s James A. Bland Houses. The playground covers 0.55 acres and includes 0.50 acres of active uses, such as basketball and handball courts, swings, and jungle gyms, as well as 0.05

acres of passive uses, such as benches. The Daniel Carter Beard Mall is a 0.66-acre passive open space with benches available for sitting.

The residential study area also includes one open space that is not under DPR jurisdiction—the Lippman Arcade, which spans the block between Roosevelt Avenue and 39th Avenue and features bench seating. The Arcade is 0.10 acres.

QUALITATIVE DISCUSSION

Six additional open spaces are located just beyond the residential study area boundary (see **Figure 5-1** and **Table 5-4**). First, the Corona Golf Playground is located within a ½-mile radius of the proposed project site, but outside of the census tract-defined study area used for the quantitative open space analysis. The Corona Golf Playground was reconstructed in 2009 and features a water play area, basketball courts, a volleyball court, and fitness equipment. Second, the Flushing Branch Library is across the street from the residential study area boundary. Residents can sit on benches outside of the library or on the library's steps. Third, Kissena Corridor West is located just east of Flushing Meadows-Corona Park and the residential study area boundary. Kissena Corridor West is the western portion of the 100-acre Kissena Corridor Park that links Flushing Meadows-Corona Park to Kissena Park. Kissena Corridor West also includes the Queens Botanical Gardens, as well as active and passive open space resources. Fourth, approximately 781 acres of Flushing Meadows-Corona Park are located beyond the study area boundary. Recreational resources within the portion of Flushing Meadows-Corona Park outside of the study area boundary include tennis courts, soccer fields, sitting areas, and other active and passive resources, including the Al Oerter Recreation Center, a 20,000 square foot recreation center that opened in 2007 and includes an indoor track, racquetball and basketball courts, as well as cardiovascular and strength equipment, in addition to afterschool, teen, and senior programmatic activities. While these remaining acres may be outside of the study area boundary, they are entirely contiguous with the portions of the park within the study area and provide a number of active and passive recreational resources for study area residents. Finally, approximately 3.92 acres of the Flushing Bay Promenade is located outside of the study area boundary; however, the remainder of the Promenade is contiguous with the portion within the study area and would be easily accessible to study area residents.

Given that these resources are located outside of the study area, they are not included in the quantitative analysis. However, it is likely that study area residents take advantage of these parks, particularly the portions of Flushing Meadows-Corona Park and the Flushing Bay Promenade that are located just beyond the study area boundary.

ADEQUACY OF OPEN SPACES

QUANTIFIED ASSESSMENT

Non-residential (¼-Mile) Study Area

As described above, the analysis of the non-residential (¼-mile) study area focuses on passive open spaces that may be used by workers and students in the area. **Table 5-5** compares the existing ratio of acres of open space per 1,000 non-residents with the City's guideline ratio of 0.15 acres per 1,000 non-residents. The passive open space ratio for the non-residential study area is 2.51 acres of passive open space per 1,000 workers, which far exceeds the City's guideline of 0.15.

Table 5-5
Existing Conditions: Adequacy of Open Space Resources

Total Population		Open Space Acreage			Open Space Ratios (Acres per 1,000 People)			City Open Space Guidelines		
		Total	Active	Passive	Total	Active	Passive	Total	Active	Passive
Non-residential (¼-Mile) Study Area										
Workers	4,406	22.11	11.06	11.06	N/A	N/A	2.51	N/A	N/A	0.15
Residential (½-Mile) Study Area										
Residents	30,048	140.07	73.97	66.11	4.66	2.46	2.14	2.5	2.0	0.5

Residential (½-Mile) Study Area

The quantitative assessment of the adequacy of open space resources within the residential (½-mile) study area considers the ratios of active, passive, and total open space acreage per 1,000 residents. The residential study area has a total of approximately 137.91 acres of open space, including 73.53 acres of active space and 64.39 acres of passive space. With an estimated residential population of 30,048, the residential study area has a total open space ratio of 4.59 acres per 1,000 residents. This is substantially higher than the City's planning goal of 2.5 total active and passive acres per 1,000 residents and also much higher than the City's median of 1.5 total acres per 1,000 residents.

The residential study area has a passive open space ratio of 2.14 acres of passive open space per 1,000 residents, which is above the City's benchmark of 0.5 acres of passive space per 1,000 residents. The area's active open space ratio is 2.45 acres per 1,000 residents, which exceeds the City's planning goal of 2.0 acres per 1,000 residents.

QUALITATIVE DISCUSSION

The resources described above that are located just beyond the residential study area boundary are likely utilized by residents and workers within the residential study area. This is particularly true for Flushing Meadows-Corona Park, a flagship park that draws people from throughout the City. The park's resources that were not included in the quantitative analysis include soccer fields and tennis courts, open fields that could be used for both passive and active use, and the Al Oerter Recreation Center. Even though these resources are located just beyond the study area boundary, residents would be able to easily utilize them due to their proximity to the study area and direct connection to the portion of the park located within the study area boundaries.

As shown in **Table 5-3** above, children ages 4 and younger in the residential study area comprise approximately 7.7 percent of the residential population. This proportion is higher than that of Queens (5.9 percent) and New York City (6.3 percent). Children in this cohort typically use traditional playgrounds that have play equipment for toddlers and preschool-aged children. Facilities in the study area offering such amenities include Bland Playground and Louis Armstrong Playground.

Children between the ages of 5 and 9 account for approximately 6.3 percent of the residential population in the residential study area (see **Table 5-3** above). This percentage is higher than the percentage for this age cohort in Queens (5.5 percent) and New York City (5.8 percent). Children ages 5 to 9 use traditional playgrounds with play equipment suitable for school-aged children, as well as grassy and hard-surfaced open spaces which are important for ball playing, running, skipping rope, and other active play. Within the study area, playgrounds such as Bland Playground and Louis Armstrong Playground, and other park and recreation spaces including

Flushing Meadows-Corona Park, Flushing Bay Promenade, and Flushing Meadows-Corona Park Aquatic Center include amenities appropriate for this age cohort.

Approximately 5.1 percent of residents in the residential study area are children between the ages 10 and 14 (see **Table 5-3** above). This proportion is less than the percentage represented by this age cohort in Queens (5.5 percent) and New York City (5.7 percent). Children between the ages of 10 and 14 tend to use playground equipment, court spaces, little league fields, and ball fields. Facilities in the study area offering such amenities include Bland Playground, Louis Armstrong Playground, Flushing Meadows-Corona Park, Flushing Bay Promenade, and Flushing Meadows-Corona Park Aquatic Center.

Teenagers and young adults between the ages of 15 and 19 account for approximately 6.2 percent of the residential study area population, a proportion that matches the proportion in Queens (6.2 percent) and is slightly lower than New York City (6.6 percent). Teenagers and young adults tend to utilize court facilities and active fields. Within the study area, Flushing Meadows-Corona Park, Flushing Bay Promenade, and Flushing Meadows-Corona Park Aquatic Center serve this age cohort.

The working-age population (ages 20 to 64) accounts for the largest percentage of the population in the residential study area (approximately 68.0 percent). This is a higher proportion than that for this age cohort in Queens (63.9 percent) and New York City (63.5 percent). This age cohort tends to use facilities for sports and active fields, as well as paths and other facilities that encourage individualized recreation. The facilities mentioned above as serving teenagers and young adults would also serve the working-age population.

The senior population (ages 65 and above) comprises approximately 6.7 percent of the residential study area's population. This represents almost half of the percentages for Queens (12.8 percent) and New York City (12.1 percent). Senior citizens tend to utilize facilities for active recreation like handball, tennis, gardening, and swimming, as well as passive recreational facilities. Within the study area, the senior population is served by various facilities for active recreation as well as facilities for passive use, including the Daniel Carter Beard Mall and Lippman Arcade.

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

The assessment of the No Action condition examines conditions that are expected to occur in the study area by 2018, 2028, and 2032, absent the proposed project. The capacity of open space resources to serve future populations in the study area is examined using quantitative and qualitative factors.

2018

STUDY AREA POPULATION

Non-residential (1/4-Mile) Study Area

Absent the proposed project, the non-residential study area will continue to experience residential, commercial, and institutional development. As described in detail in Chapter 2, "Land Use, Zoning, and Public Policy," by 2018, several No Action projects will be built in the non-residential study area. These projects are listed in Table 2-2 and their locations are shown in Figure 2-4.

Willeys Point Development

The known development projects will result in an estimated total of 246 new workers in the non-residential study area by 2018.¹ Based on these projects and the existing populations, the non-residential study area would have an estimated 4,652 workers in 2018.

Residential (1/2-Mile) Study Area

New development in the residential study area will introduce a total of 3,684 residential units, adding an estimated 10,389 residents.² The residential population in the residential study area in the No Action condition is estimated to be 40,437.

No substantial changes to the age distribution of the residential population are expected by 2018. Therefore, the estimated number of residents in each age cohort as shown in **Table 5-6** is based on the percent share for that age cohort at the time of the 2010 U.S. Census.

Table 5-6
2018 No Action Condition: Residential Population Age Distribution

Age Category	Persons	Percent
4 and younger	3,119	7.7%
5 to 9	2,546	6.3%
10 to 14	2,052	5.1%
15 to 19	2,496	6.2%
20 to 64	27,515	68.0%
65 and over	2,708	6.7%
Total	40,437	100.0%
Source: U.S. Census 2010, AKRF, Inc.		

STUDY AREA OPEN SPACES

Non-residential (1/4-Mile) Study Area

In the No Action condition, no notable changes are expected to the portions of Flushing Meadows-Corona Park that would be directly affected by the proposed project (i.e., the surface parking lots surrounding CitiField, which are mapped parkland).

There are no known planned or proposed open space projects in the non-residential study area. The New York City Department of Transportation is considering potential bicycle path and pedestrian access improvements to the Flushing Bay Promenade from Flushing, and some City capital funding has been allocated for streetscape improvements on Roosevelt Avenue west into Corona; however, there are no specific designs or timeline for implementation for either proposal.

¹ For all planned projects with the exception of the Major League Soccer (MLS) stadium, employment density ratios were applied to the expected square footage for each use to estimate future employment. The ratios used assume one worker each per: 25 residential units; 400 sf of retail space; 3.11 hotel rooms; 250 sf of general office space; 450 sf of medical office space; 1,000 sf of community facility space; 1,000 sf of industrial space or other commercial space (not retail or office); 11 school seats; and 50 parking spaces. Estimated full-time employment at the MLS stadium (165) was provided by EDC. An additional estimated 700 part-time stadium workers were not included in this analysis, as part-time workers would be present only on event days.

² Estimate of new residents based on an average household size of 2.82 for Queens (2010 Census).

Residential (1/2-Mile) Study Area

Within Flushing Meadows-Corona Park, there is a proposal to construct a new stadium for professional soccer purposes on the present site of the Fountain of the Planets and land surrounding the fountain. As currently contemplated, a 25,000-seat capacity stadium with the ability to be expanded to 35,000 seats would be constructed on an area of between 10 and 13 acres. In addition to the fountain, the stadium would displace four existing soccer fields, a basketball court, landscaped areas, and pathways, which would be relocated to other locations within the park. Both New York State alienation legislation and Land and Water Conservation Fund Act considerations will require the provision of replacement park land for this project. Approximately 7.37 acres of the MLS stadium site is located within the proposed project's 1/2-mile study area. Of that, 0.59 acres are currently occupied by active open space (soccer fields) and 6.78 acres are occupied by passive open space (Industry Pond and paved walkways).

Also within Flushing Meadows-Corona Park, a series of recreational improvements will be implemented as part of DPR's ongoing capital projects program. Overall, four soccer fields are anticipated to be improved, new volleyball courts are expected to be created, and DPR has identified repair and resurfacing of Porpoise Bridge, including repair of its tide gates, as a priority project.

*ADEQUACY OF OPEN SPACES**Quantitative Assessment**Non-residential (1/4-Mile) Study Area*

Absent the proposed project, by 2018, the number of workers in the non-residential study area is expected to increase to 4,652 and the total amount of open space is expected to remain at 22.11 acres, including 11.06 acres of passive open space. With the addition of new worker population in the No Action condition, the passive open space ratio for the non-residential study area would decrease from 2.51 to 2.38 acres per 1,000 non-residents (see **Table 5-7**). This would remain well above the City's guideline for this ratio of 0.15 acres per 1,000 non-residents.

Table 5-7
2018 No Action Condition: Adequacy of Open Space Resources

Total Population		Open Space Acreage			Open Space Ratios (Acres per 1,000 People)			City Open Space Guidelines		
		Total	Active	Passive	Total	Active	Passive	Total	Active	Passive
Non-residential (1/4-Mile) Study Area										
Workers	4,652	22.11	11.06	11.06	N/A	N/A	2.38	N/A	N/A	0.15
Residential (1/2-Mile) Study Area										
Residents	40,437	130.54	72.94	57.61	3.23	1.80	1.42	2.5	2.0	0.5

Residential (1/2-Mile) Study Area

In the No Action condition, the increase in residents would decrease the total open space ratio from 4.59 to 3.23 acres per 1,000 residents. The active open space ratio would decrease from 2.45 to 1.80 acres per 1,000 residents, and the passive open space ratio would decrease from 2.14 to 1.42 acres per 1,000 residents. All three ratios would remain above the City's goals.

Qualitative Assessment

In the future without the proposed project, residents and workers will continue to be well served by open space. Park improvements implemented as part of DPR's ongoing capital projects

program will enhance the appearance and functionality of several spaces within Flushing Meadows-Corona Park, and study area residents will continue to have access to open spaces just outside the study area.

2028

STUDY AREA POPULATION

There are no known projects or open space improvements planned or proposed for completion by 2028 in the non-residential or residential study areas.

STUDY AREA OPEN SPACES

Non-residential (¼-Mile) Study Area

In the No Action condition, no notable changes are expected to the portions of Flushing Meadows-Corona Park that would be directly affected by the proposed project (i.e., the surface parking lots surrounding CitiField, which are mapped parkland).

There are no known planned or proposed open space projects in the non-residential study area.

Residential (½-Mile) Study Area

There are two open space improvements in the residential study area planned for completion by 2028. The first is 1.52 acres of passive open space planned as part of the Flushing Commons development in downtown Flushing (location shown in **Figure 5-1**). The second is the USTA National Tennis Center Strategic Vision. By 2019, this project would improve the NTC site plan, circulation, visitor amenities, and landscaping, and also would construct two new stadiums to replace the existing Louis Armstrong Stadium and Grandstand Stadium. The proposed project would also include modifications to tournament courts and ancillary buildings, possible improvements to Arthur Ashe Stadium, the construction of two new parking garages, the relocation of a connector road, and pedestrian enhancements. To accommodate the NTC Strategic Vision project, up to ~~1.02~~ 0.94 acres of land would be added to the NTC site, including 0.68-acres of park land that would be alienated, and 0.26-acres of previously alienated park land that is ~~outside the current~~ currently not included in the lease. Improvements to active recreation features in Flushing Meadows-Corona Park would also be provided. The project would add approximately 100 workers during the U.S. Open; however, employment would remain unchanged during the other eleven months of the year. The project is expected to be completed by 2019. Although the NTC Strategic Vision project would involve alienation of 0.68 acres of park land and reconfiguration of existing stadium and court space, the land utilized by the NTC would remain mapped parkland and would remain publicly accessible in the same way the rest of the NTC is publicly accessible, and replacement park land in two parcels totaling 1.56 acres would be surrendered from within the current boundaries of the NTC in connection with the alienation of the 0.68-acre parcel. Therefore, the NTC Strategic Vision project is not included below in the quantitative assessment of the adequacy of open spaces.

Aside from Flushing Commons and the NTC Strategic Vision project, there are no known open space improvements or development projects planned or proposed for completion by 2028 in the non-residential or residential study areas.

ADEQUACY OF OPEN SPACES

Quantitative Assessment

Non-residential (1/4-Mile) Study Area

Population and open space ratios would remain the same in the 2028 No Action condition as described for the 2018 No Action condition (see **Table 5-8**).

Table 5-8
2028 No Action Condition: Adequacy of Open Space Resources

Total Population		Open Space Acreage			Open Space Ratios (Acres per 1,000 People)			City Open Space Guidelines		
		Total	Active	Passive	Total	Active	Passive	Total	Active	Passive
Non-residential (¼-Mile) Study Area										
Workers	4,652	22.11	11.06	11.06	N/A	N/A	2.38	N/A	N/A	0.15
Residential (½-Mile) Study Area										
Residents	40,437	132.06	72.94	59.13	3.27	1.80	1.16	2.5	2.0	0.5

Residential (1/2-Mile) Study Area

In the No Action condition, the increase in passive open space at Flushing Commons would increase the total open space ratio from 3.23 to 3.27 acres per 1,000 residents. The active open space ratio would remain the same at 1.80 acres per 1,000 residents, and the passive open space ratio would increase from 1.42 to 1.46 acres per 1,000 residents. All three ratios would remain above the City's goals.

Qualitative Assessment

In the future without the proposed project, residents and workers will continue to be well served by open space.

2032

There are no known projects or open space improvements planned or proposed for completion by 2032 in the non-residential or residential study areas. Therefore, population and open space estimates and open space ratios would remain the same in the 2032 No Action condition as described for the 2028 No Action condition.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

The assessment of the With Action condition examines conditions that are expected to occur as a result of the RWCDs by each of the three analysis years (2018, 2028, and 2032). The capacity of open space resources to serve future populations in the study area is examined using quantitative and qualitative factors. The potential for direct effects on open space is also considered.

DIRECT EFFECTS

As described above, direct adverse effects on an open space occur when a proposed action would cause the physical loss of public open space; change the use of an open space so that it no longer serves the same user population; limit public access to an open space; or cause increased noise or air pollutant emissions, odors, or shadows that would affect its usefulness, whether on a permanent or temporary basis.

Willets Point Development

The proposed project would not have any adverse impacts on existing open space in terms of air quality, noise, or shadows in any of the three build years analyzed (see Chapter 6, “Shadows,” Chapter 15, “Air Quality,” and Chapter 17, “Noise,” for additional information). Noise associated with traffic generated by the proposed project and its associated parking facilities would not be expected to result in any significant increases in noise levels, including at World’s Fair Marina Park, which was predicted to experience a significant adverse noise impact in the 2008 FGEIS during the Saturday midday time period. Noise levels in the newly created open spaces would be greater than prescribed by CEQR criteria, but would be comparable to other parks around New York City and would not constitute a significant adverse impact. The Willets West development would cast new shadows of very limited extent and duration on nearby landscaped traffic islands and a portion of an area containing trees in the winter only, and these would not cause significant adverse shadow impacts. The proposed project would not cause increased noise or air pollutant emissions or odors that would affect the usefulness of existing or newly created open spaces.

PHASE 1A (2018)

Phase 1A of the proposed project (Willets West) would build upon 30.7 acres west of surface parking located west of CitiField. While this land is mapped as parkland, it does not function as recreational open space. The land was occupied by Shea Stadium and associated parking and circulation space until it was replaced by CitiField in 2009, and it is now occupied exclusively by surface parking. There is one event—the Major League Wheelchair Softball Tournament—that is held in this area; however, this is not an event that provides open space on a constant and regular basis for designated daily periods. This use is therefore not considered a public open space use as defined under CEQR. Furthermore, the Major League Wheelchair Softball Tournament would be relocated to the Special Willets Point District in Phase 1A of the proposed project. Therefore, developing this mapped parkland has no effect on the adequacy of open space for the study area residential and non-residential populations.

The Willets West portion of the project site contains traffic islands within and around the perimeter of the surface parking area, which are currently planted with trees. It is anticipated that some of these trees would require removal for construction of the proposed project. Likewise, it is anticipated that trees located on the westernmost CitiField surface parking lot south of Roosevelt Avenue would be removed for construction of a structured parking facility for CitiField. Tree removal and replacement would be conducted in conformance with DPR requirements, including approval from DPR’s Queens forestry division.

PHASE 1B (2028)

Phase 1B of the proposed project would not directly displace any public open spaces. It is anticipated that trees located within traffic islands on portions of the CitiField leasehold along Roosevelt Avenue (South Lot and Lot D) would need to be removed for construction of structured parking. Tree removal and replacement would be conducted in conformance with DPR requirements, including approval from DPR’s Queens forestry division.

PHASE 2 (2032)

Phase 2 of the proposed project would not directly displace any public open spaces. By 2032, it is assumed that Lot B would also be developed for office, retail, and parking uses. While this land is mapped as parkland, it does not function as recreational open space. The land has been

occupied by Shea Stadium- and CitiField-associated parking and circulation space since approximately 1964. Therefore, developing this mapped parkland has no effect on the adequacy of open space for the study area residential and non-residential populations.

All phases of project would provide pedestrian access from 126th Street to the MTA-owned sites along Flushing Creek, should they be developed with public open space in the future. For Phase 1A of the project, an 8-foot corridor would be provided between the parking lot and Roosevelt Avenue to provide potential future pedestrian access between 126th Street and the MTA parcels. For Phases 1B and 2 of the project, in compliance with the regulations of the Special Willets Point District, a 40-foot pedestrian amenity corridor between 126th Street and the MTA parcels would replace the 8-foot corridor, providing for continuous access to the MTA parcels.

INDIRECT EFFECTS

STUDY AREA POPULATION

Phase 1A (2018)

Non-Residential (1/4-Mile) Study Area

The proposed project would introduce approximately 3,671 workers to the non-residential study area by 2018. At the same time, as described in Chapter 3, “Socioeconomic Conditions,” the project would displace approximately 122 existing businesses by 2018. These businesses employ an estimated 530 workers. Accounting for new and displaced employees, the non-residential study area worker population would increase to 7,793 by 2018.

Residential (1/2-Mile) Study Area

The proposed project would not introduce any residential population by 2018. The estimated residential study area residential population would remain at 40,437.

Phase 1B (2028)

Non-Residential (1/4-Mile) Study Area

The proposed project would introduce a total of 8,237 new workers by 2028 (4,566 new workers during Phase 1B). At the same time, the remaining 98 businesses currently located on the project site would be displaced. These businesses employ an estimated 823 workers. Accounting for new and displaced employees, the non-residential study area worker population would increase to 11,583 by 2028.

Residential (1/2-Mile) Study Area

Phase 1B of the proposed project would introduce 2,490 dwelling units, with an estimated 7,022 residents, by 2028. With the addition of these new residents, the residential study area residential population would increase to 47,459 in 2028.

Phase 2 (2032)

Non-Residential (1/4-Mile) Study Area

The proposed project would introduce a total of 9,666 new workers by 2032 (1,448 new workers during Phase 2), and an additional 1,581 workers would be added in the RWCDs by the development of Lot B. With these additional workers, the non-residential study area worker population would increase to 14,602 in 2032.

Willets Point Development

Residential (1/2-Mile) Study Area

By 2032, the proposed project would introduce a total of 5,850 dwelling units, with an estimated 16,497 residents. With the addition of these new residents, the residential study area residential population would increase to 56,934 in 2032.

The age distribution of the residential population is not expected to substantially change as a result of the proposed project. **Table 5-9** shows the estimated number of residents in each age cohort, based on the percent share for that age cohort at the time of the 2010 Census.

Table 5-9
With Action Condition (2032): Residential Population Age Distribution

Age Category	Persons	Percent
4 and younger	4,392	7.7%
5 to 9	3,585	6.3%
10 to 14	2,890	5.1%
15 to 19	3,515	6.2%
20 to 64	38,740	68.0%
65 and over	3,812	6.7%
Total	56,934	100.0%

STUDY AREA OPEN SPACES

Phase 1A (2018)

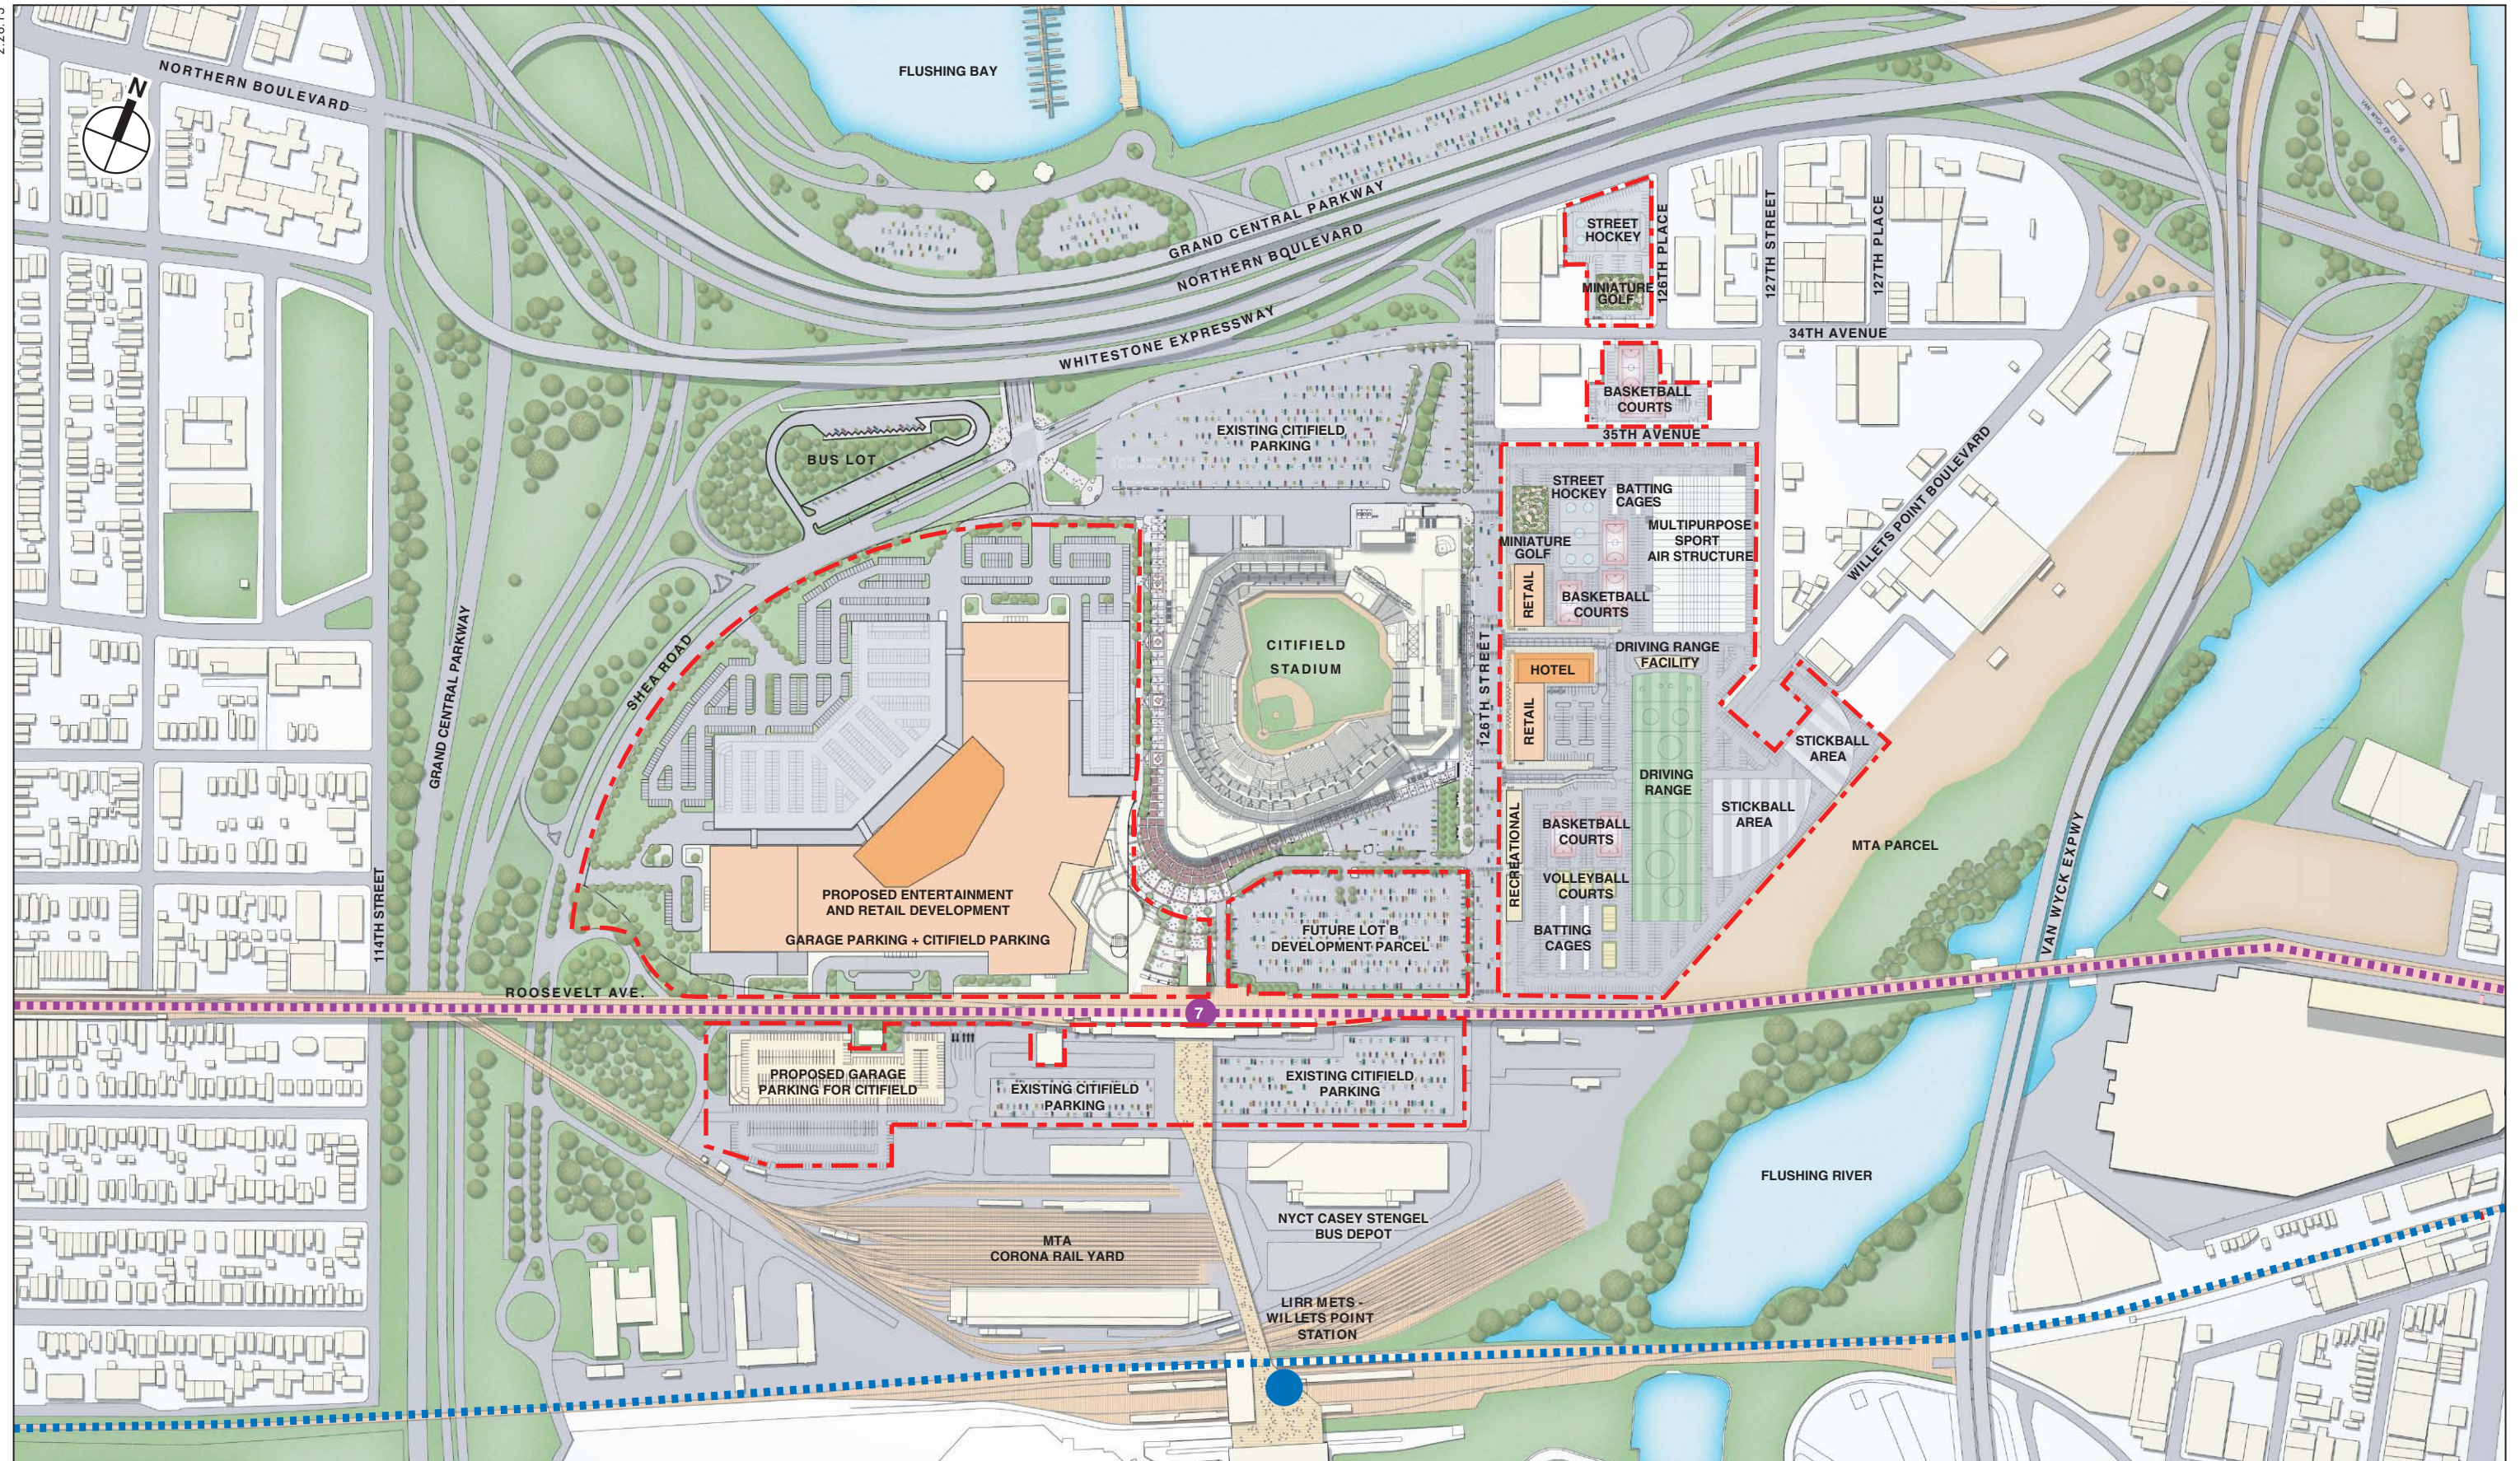

During Phase 1A of the proposed project, the parking area within the Special Willets Point District would be converted to active recreational use a minimum of six months per year. **Figure 5-2** shows an illustrative site plan for the recreational uses that could be provided during Phase 1A. As this interim parking/recreational space would only be available half the year, it is not included in the quantitative assessment of the adequacy of open space presented below. The total amount of passive open space in the non-residential study area would remain at 11.06 acres. The residential study area would continue to have a total of 130.54 acres of open space, comprised of 72.94 acres of active space and 57.61 acres of passive space.

Phase 1B (2028)

Phase 1B of the proposed project would include the development of 6 acres of privately owned, publicly accessible open space. The programming of the Phase 1B open space is currently conceptual; however, for the purposes of this analysis, it is considered to be comprised of entirely passive uses. A more detailed description of the proposed project's open space is presented below under Phase 2. With this open space, the total amount of passive open space in the non-residential study area would increase to 16.06 acres by 2028. The residential study area would have a total of 137.06 acres of open space, comprised of 72.94 acres of active space and 64.13 acres of passive space.

Phase 2 (2032)

By 2032, the proposed project would add a minimum of eight acres of privately owned, publicly accessible open space to the study area. As described in the 2008 FGEIS and per the regulations of the District, this would include an approximately two-acre park, which is assumed to be developed with primarily active recreational uses. The park would be centrally located within the residential community in the eastern part of the District. While portions of this park may

Illustrative Site Plan, Phase 1A - Recreation Plan
Figure 5-2

contain play equipment, fields, or courts used exclusively by the students of the proposed school during school hours, these recreational facilities would be publicly accessible during the remainder of the day and are therefore included in the quantitative assessment. The remaining open space within the District would be programmed primarily for passive use. The regulations of the District prescribe design standards for these publicly accessible areas and also require pedestrian amenity areas or open landscaped areas, and specify minimum dimensions of these public access areas, at various locations along the perimeter of the District. The regulations ensure that public access areas are developed in conjunction with the surrounding development by stipulating the dimensions of public access areas that must be provided along with certain developments (i.e., with developments or enlargements at least 100,000 sf in size and on zoning lots at least 200,000 sf).

Consistent with the assumptions of the 2008 FGEIS, this analysis assumes that approximately 20 percent of the approximately 8 acres of new open space (1.6 acres) to be developed within the District would be for active uses, and the remaining 80 percent (6.4 acres) would be programmed for passive use. With the proposed project, the amount of open space in the non-residential and residential study areas would increase to approximately 30.11 and 140.06 acres, respectively. The non-residential study area would have 17.46 acres of passive open space and 12.66 acres of active open space. The residential study area would have 65.53 acres of passive open space and 74.54 acres of active open space.

ADEQUACY OF OPEN SPACES

Quantitative Assessment

Phase 1A (2018): Non-Residential (¼-Mile) Study Area

In the 2018 With Action condition, the ratio of passive open space acreage per 1,000 workers would decrease compared with the 2018 No Action condition, from 2.38 to 1.42 in 2018 (see **Table 5-10**). This ratio would continue to well exceed the recommended City guideline of 0.15 acres per 1,000 non-residents.

Table 5-10
With Action Condition: Adequacy of Open Space Resources

Build Year	Total Population	Open Space Acreage				Open Space Ratios Acres per 1,000 Population			City Open Space Guidelines		
		Total	Active	Passive	Total	Active	Passive	Total	Active	Passive	
Non-residential (¼-Mile) Study Area											
2018	Workers	7,793	22.11	11.06	11.06	N/A	N/A	1.42	N/A	N/A	0.15
2028	Workers	11,538	27.11	11.06	16.06	N/A	N/A	1.39	N/A	N/A	0.15
2032	Workers	14,602	30.11	12.66	17.46	N/A	N/A	1.20	N/A	N/A	0.15
Residential (½-Mile Study Area											
2018	Residents	40,437	130.54	72.94	57.61	3.23	1.80	1.42	2.5	2.0	0.5
2028	Residents	47,459	137.06	72.94	64.13	2.89	1.54	1.35	2.5	2.0	0.5
2032	Residents	56,934	140.06	74.54	65.53	2.46	1.31	1.15	2.5	2.0	0.5

Phase 1A (2018): Residential (½-Mile) Study Area

The open space ratios for the residential study area would not change in 2018 with the project as compared to the No Action condition. The total and passive open space ratios would remain well above City guidelines, at 3.23 and 1.42 acres per 1,000 residents, respectively (see **Table 5-10**).

Willeys Point Development

The active open space ratio, at 1.80 acres per 1,000 residents, would be below the City's planning goal of 2.0.

Phase 1B (2028): Non-Residential (1/4-Mile) Study Area

In 2028, the ratio of passive open space acreage per 1,000 workers would decrease compared with the No Action condition, from 2.38 to 1.39 in 2028. This ratio would continue to well exceed the recommended City guideline of 0.15 acres per 1,000 non-residents.

Phase 1B (2028): Residential (1/2-Mile) Study Area

In 2028, the total open space ratio for the residential study area would decrease from 3.27 acres per 1,000 residents in the No Action condition to 2.89 acres per 1,000 residents in the With Action condition. The ratio would remain above City's planning goal of 2.5 acres per 1,000 residents. The active open space ratio would decrease from 1.80 to 1.55 acres per 1,000 residents, which would fall below the City's goal of 2.0. The passive open space ratio would decrease from 1.46 to 1.35, but would remain well above the goal of 0.5 acres per 1,000 residents.

Phase 2 (2032): Non-Residential (1/4-Mile) Study Area

In 2032, with the addition of proposed project and Lot B new worker populations and new proposed project passive open space, the ratio of passive open space acreage per 1,000 workers would decrease to 1.20 acres per 1,000 residents (see **Table 5-10**). This ratio would continue to well exceed the recommended City guideline of 0.15 acres per 1,000 non-residents.

Phase 2 (2032): Residential (1/2-Mile) Study Area

The total open space ratio for the residential study area would decrease in 2032 from 3.27 acres per 1,000 residents in the No Action condition to 2.46 acres per 1,000 residents in the With Action condition (see **Table 5-10**). The ratio would be just below the City's planning goal of 2.5 acres per 1,000 residents. The active open space ratio would decrease from 1.80 acres per 1,000 residents in the No Action condition to 1.31 acres per 1,000 residents in the With Action condition, which is below the City's goal of 2.0. The passive open space ratio would decrease from 1.46 to 1.15, but would remain above the goal of 0.5 acres per 1,000 residents.

Qualitative Assessment

As indicated above, the passive open space ratio would remain above City guidelines in all three of the analysis years. The total open space ratio would remain above City guidelines in 2018 and 2028. In 2032, the total open space ratio would be 2.46 acres per 1,000 residents, which would be slightly below the City guideline of 2.5. Although the active open space ratio would fall below the City's planning goal in the 2028 and 2032 With Action analysis years, the total open space ratio would remain above the Citywide median of 1.5 acres per 1,000 residents, and residents in the study area would have access to parks just outside of the study area, including Corona Golf Playground, and areas of Flushing Meadows-Corona Park and the Flushing Bay Promenade that fall outside of the study area. Both Flushing Meadows-Corona Park and the Flushing Bay Promenade would draw residents from beyond a 1/2-mile. The Flushing Meadows-Corona Park in particular serves as a destination and would draw residents from beyond a 1/2-mile to utilize the variety of passive and active open spaces that it offers.

As shown in **Table 5-3**, the study area population has a somewhat higher proportion of young children and children (ages 4 and younger and ages 5 to 9) as compared with Queens and New York City. Children in these age brackets tend to use traditional playgrounds with play equipment suitable for preschool and school age children, as well as grassy and hard-surfaced open spaces which are important for ball playing, running, skipping rope, and other active play.

Demand for these types of facilities is served within the residential study area by several playgrounds and active spaces including Bland Playground, Louis Armstrong Playground, Hinton Park, Flushing Meadows-Corona Park, Flushing Bay Promenade, and Flushing Meadows-Corona Park Aquatic Center. By 2032, the proposed project would introduce a 2-acre park in the District, which would be programmed primarily for active use and would help serve both new and existing study area children.

IMPACT SIGNIFICANCE

According to the *CEQR Technical Manual*, the significance of a project's effects on open space is assessed using both qualitative and quantitative factors. These effects are compared with those that would occur in the No Action condition to determine the effects attributable to the proposed action.

According to the *CEQR Technical Manual*, if the decrease in the open space ratio approaches or exceeds 5 percent, it is generally considered a substantial change warranting a more detailed analysis. However, the change in the open space ratio should be balanced against how well served an area is by open space. If the study area exhibits a low open space ratio, even a small decrease may warrant a detailed analysis. Likewise, if the study area exhibits an open space ratio that approaches or exceeds the planning goal of 2.5 acres, a greater percentage of change in the ratio may be acceptable.

DIRECT EFFECTS

The proposed development of the Willets West and Roosevelt Avenue portions of the project, as well as the potential development of Lot B, on land that is mapped as parkland would not constitute a significant adverse open space impact. As noted earlier, this land is occupied by paved surface parking for CitiField and does not function as either active or passive recreational open space. There is one event—the Major League Wheelchair Softball Tournament—that is held in this area; however, this is not an event that provides open space on a constant and regular basis for designated daily periods. This use is therefore not considered a public open space use as defined under CEQR. Furthermore, the Major League Wheelchair Softball Tournament would be relocated to the Special Willets Point District in Phase 1A of the proposed project. The proposed project would not result in significant adverse shadow, noise, or air quality impacts on any of the open spaces in the study area. The proposed project would activate the Willets West area, making it more appealing to residential and non-residential populations and improving connections between the study area populations and the Flushing Bay Promenade.

NON-RESIDENTIAL (1/4-MILE) STUDY AREA

As shown in **Table 5-11**, while the passive open space ratio for workers would decrease by approximately 41 and 50 percent as compared to the No Action condition in 2028 and 2032, respectively, the ratio in 2032 would be 1.20 acres of passive open space per 1,000 workers, which well exceeds the City's guideline of 0.15. Therefore, the RWCDS would not result in any significant adverse impacts to open space resources in the non-residential study area.

Table 5-11
With Action Condition: Open Space Ratios Summary

Ratio	City Guideline	Open Space Ratios (acres per 1,000 people)			Percent Change, No Action to With Action Condition
		Existing Conditions	No Action Condition	With Action Condition	
Phase 1A (2018)					
Non-Residential (¼-Mile) Study Area					
Passive/Workers	0.15	2.51	2.38	1.42	-40%
Residential (½-Mile) Study Area					
Total/Residents	2.5	4.59	3.23	3.23	0%
Active/Residents	2.0	2.45	1.80	1.80	0%
Passive/Residents	0.5	2.14	1.42	1.42	0%
Phase 1B (2028)					
Non-Residential (¼-Mile) Study Area					
Passive/Workers	0.15	2.51	2.38	1.39	-41%
Residential (½-Mile) Study Area					
Total/Residents	2.5	4.59	3.23	2.89	-11%
Active/Residents	2.0	2.45	1.80	1.54	-15%
Passive/Residents	0.5	2.14	1.42	1.35	-5%
Phase 2 (2032)					
Non-Residential (¼-Mile) Study Area					
Passive/Workers	0.15	2.51	2.38	1.20	-50%
Residential (½-Mile) Study Area					
Total/Residents	2.5	4.59	3.23	2.46	-24%
Active/Residents	2.0	2.45	1.80	1.31	-27%
Passive/Residents	0.5	2.14	1.42	1.15	-19%

RESIDENTIAL (½-MILE) STUDY AREA

No change to the open space ratios for the residential study area would take place by 2018. In the 2028 analysis year, the ratios for active, passive, and total open space in the residential study area would decrease in the With Action condition by 15 percent, 5 percent, and 11 percent, respectively. By 2032, these ratios would decrease in the With Action condition by between 19 and 27 percent (see **Table 5-11**).

Although the ratio of total open space to residents would decrease by 24 percent by 2032, at 2.46, it would still approach the City's planning goal of 2.5 acres per 1,000 residents. The population in the residential study area would continue to be well served by a mix of passive and active open space in the future with the proposed project, and therefore the RWCDS would not result in any significant adverse impacts to the total open space ratio in the residential study area.

Similarly, although the ratio of passive open space to residents would decrease by 19 percent by 2032, it would remain well above the City's planning goal of 0.5 acres per 1,000 residents, at 1.15. Therefore the RWCDS would not result in any significant adverse impacts to the passive open space ratio in the residential study area.

In contrast, the ratio for active open space in the residential study area would decrease by 15 and 27 percent compared to the 2028 and 2032 No Action conditions, respectively, and, at 1.54 and 1.31 acres per 1,000 residents, respectively, would fall below the City's planning goal of 2.0.

Although the declines in the active open space ratio between the No Action and With Action conditions in 2028 and 2032 suggest that a significant adverse impact could result, there are a number of important factors not addressed in the quantitative analysis.

First, QDG would work to incorporate ground-level, active open space and other recreational resources such as rooftop and interior programming of recreational amenities into the project design

for Phase 1B, and EDC would encourage through its formal RFP process the future developer of Phase 2 to incorporate similar features into the Phase 2 development. While these recreational amenities may be available only to tenants and residents of the site—and thus have not been included in the quantitative analysis—these amenities would help offset the burden on public active and passive resources resulting from the introduction of new users on the project site.

Second, the remainder of the most significant open space in Queens—the 898-acre Flushing Meadows-Corona Park—is not included in the quantitative analysis. This park is one of the flagship parks in the DPR inventory and draws residents from throughout the City. Residents could utilize the park’s active open space amenities and recreational facilities that are just beyond the residential study area boundary and thus were not included in the quantitative analysis. As described above, these include soccer fields and tennis courts, open fields that could be used for both passive and active use, and the Al Oerter Recreation Center.

Bicycle lanes would be required on connector streets within the redeveloped District. The bicycle lanes in the District would connect to the area-wide bicycle and greenway network, and indoor accessory bicycle parking would be required for all new residential, office, and retail uses developed in the District. Together, these measures would improve connectivity between Willets Point and surrounding areas, and provide new active recreational opportunities for area residents and visitors.

Finally, the Kissena Corridor West portion of the 100-acre Kissena Corridor Park is located just outside the residential study area to the east. This large destination park would provide additional active and passive open space resources to residents in the District.

Therefore, the RWCDs would not result in any significant adverse impacts to open space resources in the residential study area that were not previously identified in the 2008 FGEIS and subsequent technical memoranda. *

A. INTRODUCTION

This chapter assesses the potential of the proposed project to cast new shadows on surrounding public open space or other sunlight-sensitive resources. The analysis updates changes to the proposed project and background conditions since the 2008 Final Generic Environmental Impact Statement (FGEIS) and assesses whether any changed background conditions or differences in elements between the proposed project and the development program analyzed in the 2008 FGEIS and subsequent technical memoranda would result in significant adverse shadow impacts on publicly accessible open spaces, sunlight-sensitive features of historic and cultural resources, or important natural resources that were not addressed in the 2008 FGEIS or subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

The analysis concluded that the proposed parking structure in the South Lot would cast new shadows early in the mornings in all seasons onto adjacent traffic islands and a portion of an area containing trees, but that the shadows would be limited in extent and duration and would not cause significant adverse shadow impacts to these sections of Flushing Meadows-Corona Park. The Willets West development would cast new shadows of very limited extent and duration on nearby landscaped traffic islands in the winter only, and these would not cause significant adverse shadow impacts. Therefore, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in any significant adverse shadows impacts.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS analyzed the potential of proposed development within the Special Willets Point District and on Lots B and D on Roosevelt Avenue to have significant adverse shadow impacts on sunlight-sensitive resources. The 2008 FGEIS concluded that development in the District could cast some incremental shadow onto Flushing Bay, the Flushing Bay Promenade, and the Flushing River in some seasons, but the extent and duration of such incremental shadow would not be large or long enough to cause a significant adverse impact on any of these resources. In addition, the 2008 FGEIS concluded that potential future development on Lots B and D would not cause a significant adverse impact on any sunlight-sensitive resources. The subsequent technical memoranda also concluded that the proposed revisions to the Willets Point Development Plan would not have significant adverse shadow impacts.

C. DEFINITIONS AND METHODOLOGY

This analysis has been prepared in accordance with New York City Environmental Quality Review (CEQR) procedures and follows the guidelines of the 2012 *CEQR Technical Manual*.

DEFINITIONS

Incremental shadow is the additional, or new, shadow that a structure resulting from a proposed project would cast on a sunlight-sensitive resource.

Sunlight-sensitive resources are those resources that depend on sunlight or for which direct sunlight is necessary to maintain the resource's usability or architectural integrity. Such resources generally include:

- *Public open space* (e.g., parks, beaches, playgrounds, plazas, schoolyards, greenways, landscaped medians with seating). Planted areas within unused portions of roadbeds that are part of the Greenstreets program are also considered sunlight-sensitive resources.
- *Features of architectural resources that depend on sunlight for their enjoyment by the public*. Only the sunlight-sensitive features need be considered, as opposed to the entire resource. Such sunlight-sensitive features might include: design elements that depend on the contrast between light and dark (e.g., recessed balconies, arcades, deep window reveals); elaborate, highly carved ornamentation; stained glass windows; historic landscapes and scenic landmarks; and features for which the effect of direct sunlight is described as playing a significant role in the structure's importance as a historic landmark.
- *Natural resources* where the introduction of shadows could alter the resource's condition or microclimate. Such resources could include surface water bodies, wetlands, or designated resources such as coastal fish and wildlife habitats.

Non-sunlight-sensitive resources include, for the purposes of CEQR:

- *City streets and sidewalks* (except Greenstreets);
- *Private open space* (e.g., front and back yards, stoops, vacant lots, and any private, non-publicly accessible open space);
- *Project-generated open space* cannot experience a significant adverse shadow impact from the project, according to CEQR, because without the project the open space would not exist. However, a qualitative discussion of shadows on the project-generated open space should be included in the analysis.

A **significant adverse shadow impact** occurs when the incremental shadow added by a proposed project falls on a sunlight-sensitive resource and substantially reduces or completely eliminates direct sunlight, thereby significantly altering the public's use of the resource or threatening the viability of vegetation or other resources. Each case must be considered on its own merits based on the extent and duration of new shadow and an analysis of the resource's sensitivity to reduced sunlight.

METHODOLOGY

Following the guidelines of the *CEQR Technical Manual*, a preliminary screening assessment must first be conducted to ascertain whether a project's shadow could reach any sunlight-sensitive resources at any time of year. The preliminary screening assessment consists of three tiers of analysis. The first tier determines a simple radius around the proposed building

representing the longest shadow that could be cast. If there are sunlight-sensitive resources within this radius, the analysis proceeds to the second tier, which reduces the area that could be affected by project shadow by accounting for the fact that shadows can never be cast between a certain range of angles south of the project site due to the path of the sun through the sky at the latitude of New York City.

If the second tier of analysis does not eliminate the possibility of new shadows on sunlight-sensitive resources, a third tier of screening analysis further refines the area that could be reached by project shadow by looking at specific representative days in each season and determining the maximum extent of shadow over the course of each representative day.

If the third tier of analysis does not eliminate the possibility of new shadows on sunlight-sensitive resources, a detailed shadow analysis is required to determine the extent and duration of the incremental shadow resulting from the project. The detailed analysis provides the data needed to assess the shadow impacts. The effects of the new shadows on the sunlight-sensitive resources are described, and their degree of significance is considered. The results of the analysis and assessment are documented with graphics, a table of incremental shadow durations, and narrative text.

ANALYSIS FRAMEWORK

Due to its proximity to LaGuardia Airport, the Special Willets Point District is subject to height restrictions established by the Federal Aviation Administration (FAA) and the Port Authority of New York and New Jersey (PANY/NJ). Therefore, the 2008 FGEIS and subsequent technical memoranda conservatively analyzed the entire District at the maximum building envelope height allowed under these restrictions. The structures contemplated for the District in the current proposed project, including Phases 1A, 1B, and 2, fall well within the maximum building envelope height previously analyzed and approved. In addition, there have been no substantive changes to background conditions relevant to the analysis; in other words, there have been no changes to the inventory of sunlight-sensitive resources or new intervening structures. Consequently, the District does not require further analysis.

Similarly, in the 2008 FGEIS and subsequent technical memoranda the shadow screening analysis conservatively considered a maximum building envelope for the potential future development on Lot B that would be no higher than the CitiField stadium, which was approved by the FAA for 218 feet above ground level, or 232 feet above mean sea level (AMSL). This Supplemental Environmental Impact Statement (SEIS) conservatively assumes that the potential future development on Lot B would not be any taller than that which was considered for this site in the 2008 FGEIS. Therefore, no additional analysis is warranted for the Lot B structure.

The 2008 FGEIS analyzed the Lot D development as a five-story structure. As currently contemplated, the parking structure to be developed on Lot D would be 63 feet in height, similar to the parking structures on the South Lot. Therefore, this analysis conservatively included the 63-foot structure in the analysis.

The proposed “Willets West” development on the surface parking lot west of the CitiField stadium is a new element of the project since the 2008 FGEIS. This proposed structure would reach a maximum height of 104.67 feet and therefore requires a shadows assessment. The proposed South Lot parking facilities are also new to the project since the 2008 FGEIS. These two structures would reach a maximum height of 63 feet and consequently also require a shadows assessment.

D. PRELIMINARY SCREENING ASSESSMENT

A base map was developed using Geographic Information Systems (GIS)¹ showing the location of the proposed structures and the surrounding street and park layout (see **Figure 6-1**). In coordination with the open space, historic and cultural resources, and natural resources assessments presented in other chapters of this EIS, potential sunlight-sensitive resources were identified and shown on the map.

TIER 1 SCREENING ASSESSMENT

For the Tier 1 assessment, the longest shadow that a proposed structure could cast is calculated, and, using this length as the radius, a perimeter is drawn around the structure. Anything outside this perimeter representing the longest possible shadow could never be affected by project generated shadow, while anything inside the perimeter needs additional assessment.

Figure 6-1 shows the proposed structures for analysis with their heights. Most of the Willets West structure to be developed in Phase 1A (2018) would have a height of 73.67 feet, with lower elements in the northwest and northeast portions at 51 and 40 feet respectively, and a central element at 104.67 feet. The two parking structures in the South Lot, and the parking structure in Lot D, would each be 63 feet in height. These structures would be developed in Phases 1A (2018) and 1B (2028).

Within the CEQR analysis framework, the longest shadow a structure can cast occurs on December 21 at the start of the analysis day at 8:51 AM, and its length is equal to 4.3 times the structure's height. Diagram A on **Figure 6-1** shows the longest shadow study area for each structure, or in the case of Willets West, each structure part that has a consistent roof height. For example, the longest shadow study areas for each of the three 63-foot-high structures in the South Lot and Lot D would be a perimeter around each structure with a radius of 270.9 feet (63' x 4.3). For Willets West, the longest shadow that the tallest portion in the center of the proposed structure could cast would be 450 feet, and a perimeter with a radius of 450 feet is delineated around that portion of the structure. The portion of Willets West that is 73.67 feet high would have a longest shadow study area with a radius of 316.8 feet, and the shorter portions of Willets West would have longest shadow study areas with radii of 204 and 172 feet.

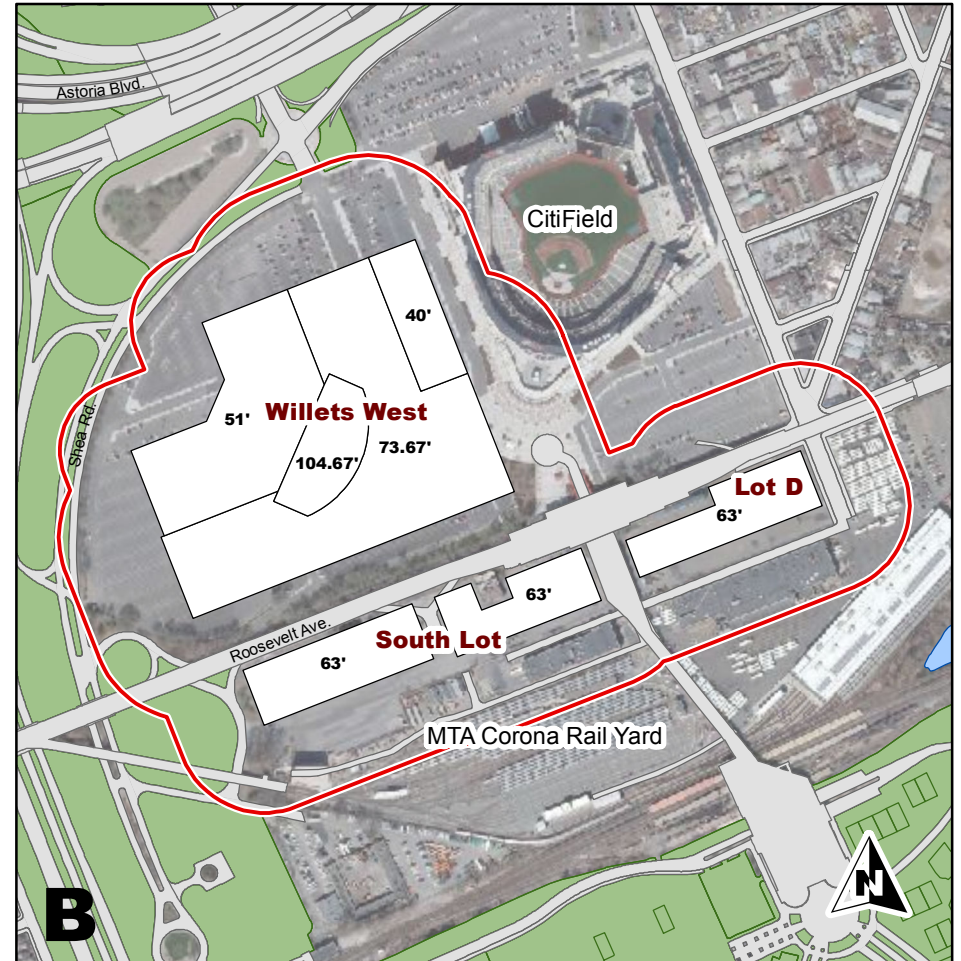

Diagram B on **Figure 6-1** shows the combined perimeters that together form the longest shadow study area for the proposed structures for analysis.

Small portions of traffic islands and an area containing trees, located between Shea Road, Roosevelt Avenue, and the access roads connecting them, are within the longest shadow study area. Therefore, the next tier of assessment was conducted.

TIER 2 SCREENING ASSESSMENT

Because of the path that the sun travels across the sky in the northern hemisphere, no shadow can be cast in a triangular area south of any given structure. In New York City this area lies between -108 and +108 degrees from true north. The complementing area north, east, and west of each structure within the longest shadow study area represents the remaining area that could potentially experience new project-generated shadow.

¹ Software: Esri ArcGIS 10.1; Data: New York City Department of Information Technology and Telecommunications (DoITT) and other City agencies, and AKRF site visits.

- Proposed structures for analysis (labeled with roof heights)
- Publicly-accessible open space or landscaped medians (outside project site boundary)
- Longest shadow study area boundary

0 200 400 600 800 1,000 Feet

Diagrams A and B, above, show the proposed structures for analysis with their heights: most of the Willets West development would have a height of 73.67 feet, with lower elements in the northwest and northeast portions at 51 and 40 feet respectively, and a central element at 104.67 feet. The two parking structures in the South Lot, and the parking structure in Lot D, would each be 63 feet in height.

Within the CEQR analysis framework, the longest shadow a structure can cast occurs on December 21 at the start of the analysis day at 8:51 AM, and its length is equal to 4.3 times the structure's height. Diagram A shows the longest shadow study area for each structure, or in the case of Willets West, each structure part that has a consistent roof height. For example, the longest shadow study areas for each of the three 63' high structures in the South Lot and Lot D would be a perimeter around each structure with a radius of 270.9 feet (63×4.3). For Willets West, the longest shadow that the tallest portion in the center of the proposed development could cast would be 450 feet, and a perimeter with a radius of 450 feet is delineated around that portion of the structure. The portion of Willets West that is 73.67 feet high would have a longest shadow study area with a radius of 316.8 feet, and the shorter portions of Willets West would have longest shadow study areas with radii of 204 and 172 feet.

Diagram B shows the combined perimeters that together form the longest shadow study area for the proposed structures for analysis.

The Tier 2 assessment only eliminated the possibility of new shadows on a very small portion of the traffic island between the South Lot and Shea Road, south of Roosevelt Avenue. The remaining longest shadow study area still contained small portions of landscaped traffic islands adjacent to Shea Road and Roosevelt Avenue. Therefore, a Tier 3 assessment was required.

TIER 3 SCREENING ASSESSMENT

The direction and length of shadows vary throughout the course of the day and also differ depending on the season. In order to determine whether project-generated shadow could fall on a sunlight-sensitive resource, three-dimensional (3D) computer mapping software² is used in the Tier 3 assessment to calculate and display the proposed project's shadows on individual representative days of the year. A computer model was developed containing three-dimensional representations of the elements in the base map used in the preceding assessments, the topographic information of the study area, and a reasonable worst-case three-dimensional representation of the proposed project.

REPRESENTATIVE DAYS FOR ANALYSIS

Following the guidance of the *CEQR Technical Manual*, shadows on the summer solstice (June 21), winter solstice (December 21) and spring and fall equinoxes (March 21 and September 21, which are approximately the same in terms of shadow patterns) are modeled, to represent the range of shadows over the course of the year. An additional representative day during the growing season is also modeled, generally the day halfway between the summer solstice and the equinoxes, i.e. May 6 or August 6, which have approximately the same shadow patterns.

TIMEFRAME WINDOW OF ANALYSIS

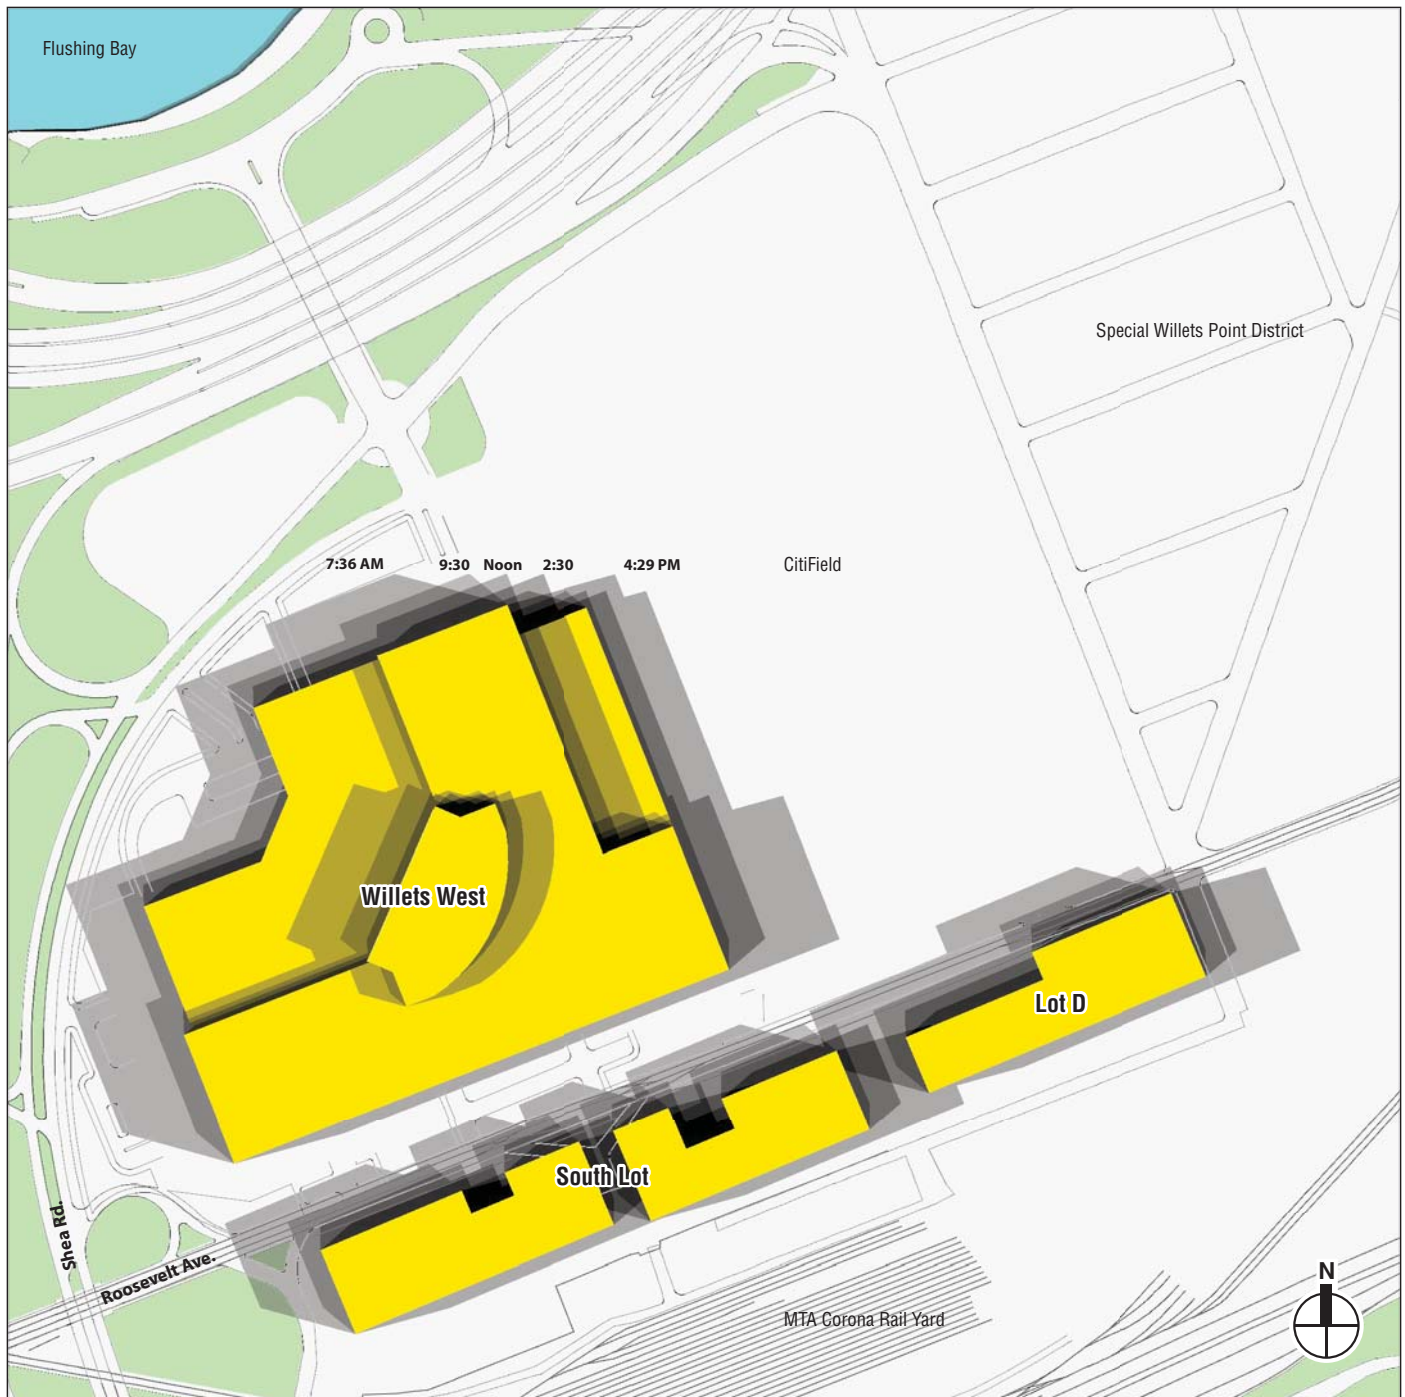

The shadow assessment considers shadows occurring between one and a half hours after sunrise and one and a half hours before sunset. At times earlier or later than this timeframe window of analysis, the sun is down near the horizon and the sun's rays reach the earth at very tangential angles, diminishing the amount of solar energy and producing shadows that are very long, move fast, and generally blend with shadows from existing structures until the sun reaches the horizon and sets. Consequently, shadows occurring outside the timeframe window of analysis are not considered significant under CEQR, and their assessment is not required.

TIER 3 SCREENING ASSESSMENT RESULTS

Figures 6-2 through 6-5 illustrate the range of shadows that would occur, in the absence of intervening buildings, from the proposed Willets West, South Lot and Lot D structures on the four representative days for analysis. As they move east and clockwise over the landscape, the shadows are shown occurring approximately every two hours from the start of the analysis day (one and a half hours after sunrise) to the end of the analysis day (one and a half hours before sunset).

The Tier 3 assessment showed that shadows from the Willets West structure would not fall on any sunlight-sensitive areas on the three analysis days of the growing season. On the December 21 analysis day, small incremental shadows would fall on portions of the adjacent landscaped

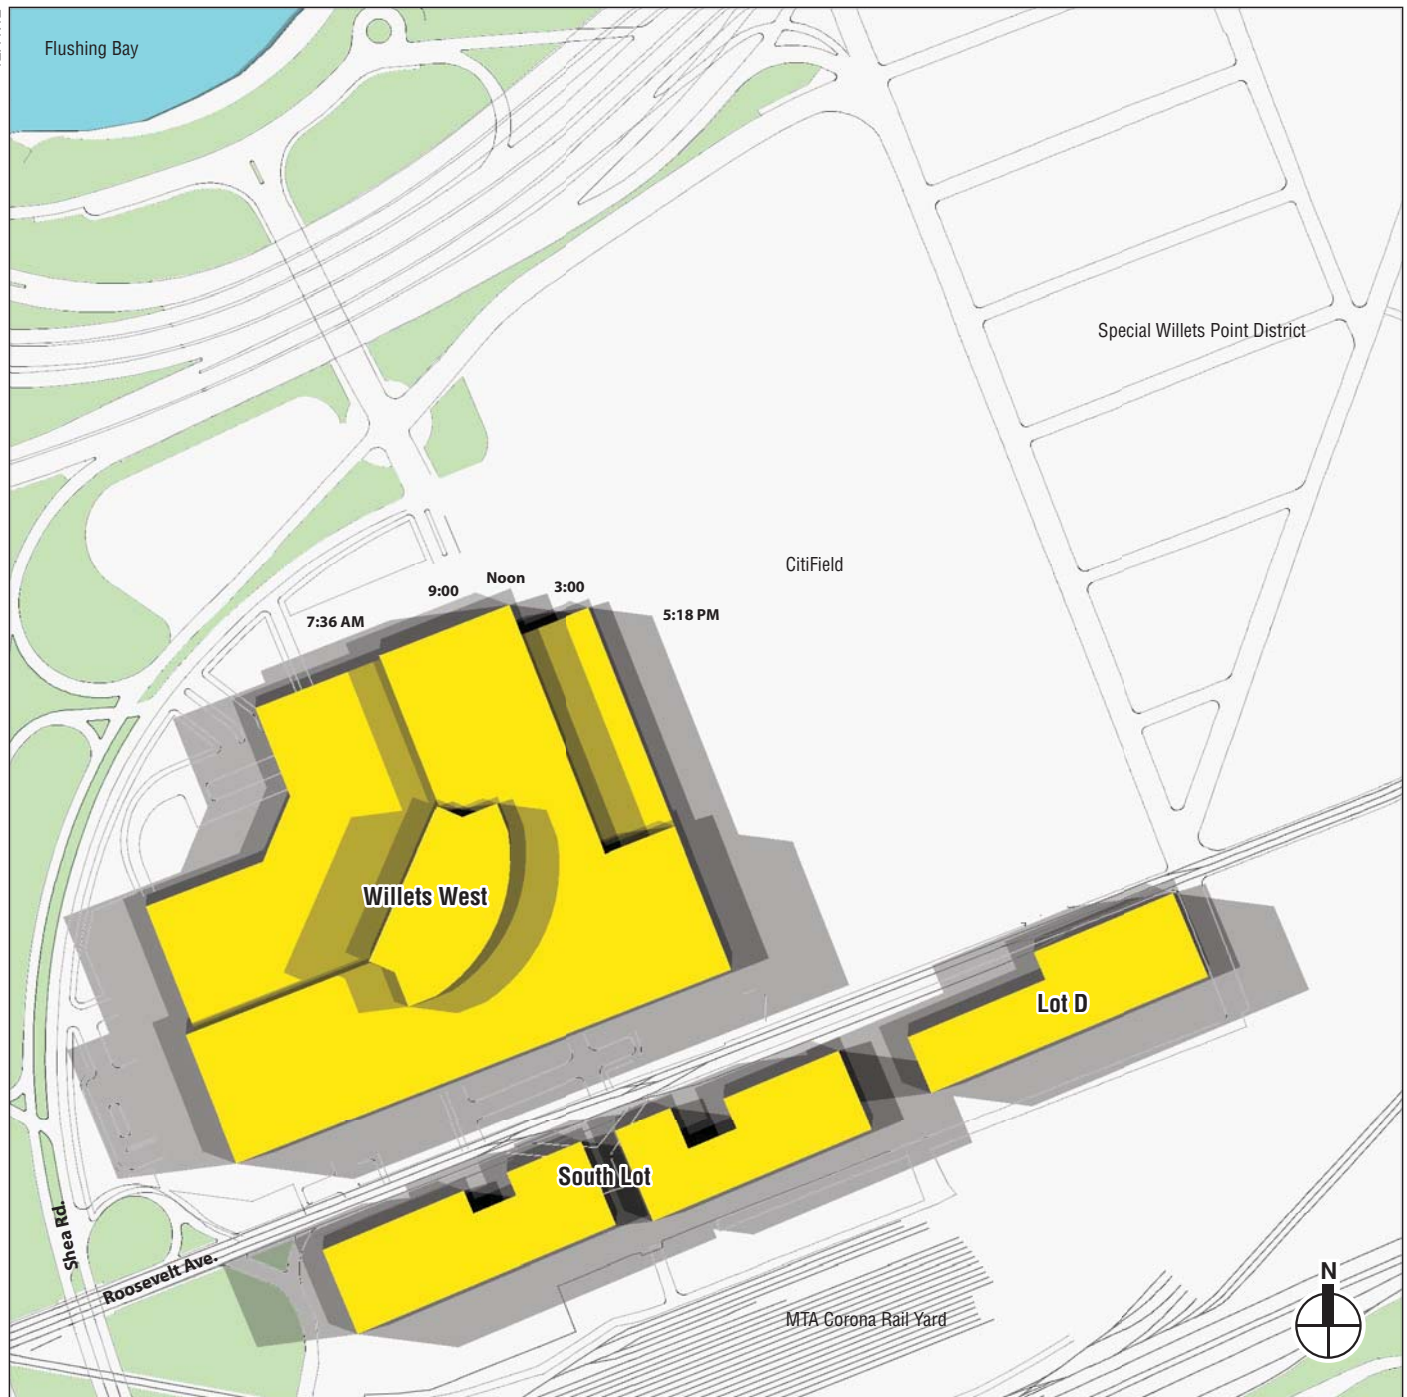

² MicroStation V8i (SELECTSeries 3).

Note: Daylight Saving Time not used.

- Proposed Buildings for Analysis*

traffic islands at the start of the analysis day. However, per CEQR guidelines, these landscaped features would be only minimally sensitive to sun and shadows in the winter.

The western of the two proposed parking structures on the South Lot would cast new shadow on the adjacent areas of the park to its immediate west in the morning on all four analysis days.

The proposed parking structure on Lot D would not cast shadows on any sunlight-sensitive resources at any time of year.

A detailed analysis was consequently warranted to determine the duration and extent of new shadows from the South Lot parking structure on the four analysis days, and from the Willets West structure on December 21.

E. DETAILED SHADOW ANALYSIS

The purpose of the detailed analysis is to determine the extent and duration of new incremental shadows that fall on sunlight-sensitive resources as a result of the project, and to assess their effects. A baseline or future No Action condition is established, containing existing buildings and sunlight-sensitive resources and any future developments planned in the area, to illustrate the baseline shadows from buildings and other structures in the study area defined in the preliminary assessment. The future condition with the proposed project and its shadows can then be compared to the shadows from the No Action condition, to determine the incremental shadows that would result with the proposed project.

Three-dimensional representations of the existing buildings in the study area were developed and added to the three-dimensional model used in the Tier 3 assessment.

Shadows are in constant movement. The computer simulation software produces an animation showing the movement of shadows over the course of each analysis period. The analysis determines the time when incremental shadow would enter each resource, and the time it would exit. Shadow analyses were performed for each of the representative days and analysis periods indicated in the Tier 3 assessment.

Table 6-1 summarizes the entry and exit times and total duration of incremental shadows on each affected sunlight-sensitive resource. The extent and duration of incremental shadows are described for each analysis day below. Because there are no intervening structures between the Willets West and South Lot developments and the landscaped traffic islands onto which they would cast new shadow, **Figures 6-2** to **6-5** serve to show the extent and movement of incremental shadows that would occur.

Table 6-1
Incremental Shadow Durations

Analysis Day and Timeframe Window	March 21 / Sept. 21 7:36 AM-4:29 PM	May 6 / August 6 6:27 AM-5:18 PM	June 21 5:57 AM-6:01 PM	December 21 8:51 AM-2:53 PM
Traffic islands and parkland west of South Lot	7:36 AM-8:50 AM Total: 1 hr 14 min	6:27 AM-8:25 AM Total: 1 hr 58 min	5:57 AM-8:15 AM Total: 2 hr 17 min	8:51 AM-9:00 AM Total: 9 min
Landscaped traffic islands adjacent to Shea Road north of Roosevelt Avenue	—	—	—	8:51 AM-9:10 AM Total: 19 min
Notes: Table indicates entry and exit times and total duration of incremental shadow for each sunlight-sensitive resource. Per <i>CEQR Technical Manual</i> guidelines, daylight saving time is not used; times are Eastern Standard Time. However, as Eastern Daylight Time is in effect for the March/September, May/August and June analysis periods, add one hour to the given times to determine the actual clock time.				

MARCH 21/SEPTEMBER 21

At the start of the March 21/September 21 analysis day at 7:36 AM, incremental shadow from the South Lot structure would fall to the west on a small area of parkland containing grass and trees. The incremental shadow would move east, exiting the larger section of parkland, located a bit further west and south, 34 minutes later at 8:10 AM and the smaller traffic island at 8:50 AM (see **Figure 6-2**).

MAY 6/AUGUST 6

At the start of the May 6/August 6 analysis day at 6:27 AM, incremental shadow from the South Lot structure would fall to the west on the same two areas of the park, the small traffic island to the northwest and the larger area of grass and trees to the west. The incremental shadow would move east, exiting the larger area at 7:25 AM and the small traffic island at 8:25 AM (see **Figure 6-3**).

JUNE 21

At the start of the June 21 analysis day at 5:57 AM, incremental shadow from the South Lot structure would fall to the west on the same two portions of adjacent parkland. The incremental shadow would move east, exiting the larger area at 7:15 AM and the small traffic island at 8:15 AM (see **Figure 6-4**).

DECEMBER 21

Shadow from the Willets West structure would fall on small portions of the landscaped traffic islands along Shea Road to the northwest for the first nine minutes of the analysis day.

Shadow from the South Lot structure would fall on a small portion of a landscaped traffic island for the first 19 minutes of the analysis day.

F. CONCLUSIONS

The areas of parkland west and northwest of the South Lot parking structure would receive new shadows during the months of the growing season, ranging between an hour and a quarter in early spring and early fall, to two and a quarter hours on June 21. The new shadows would be small in extent, and would move, affecting different plants at different times during the affected period. These areas of parkland would continue to get more than seven hours of direct sun even in March and September, because there are no structures to their south and west. Consequently, the new shadows from the proposed project would not cause significant adverse shadow impacts to these areas of Flushing Meadows-Corona Park. The nine minutes of new shadow in the winter that would be cast by the Willets West structure would not cause a significant adverse impact to the traffic islands along Shea Road north of Roosevelt Avenue. Therefore, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in any significant adverse shadows impacts. *

A. INTRODUCTION

This chapter assesses the potential of the proposed project to affect historic and cultural resources. The analysis updates changes to the proposed project and background conditions since the 2008 FGEIS and assesses whether any changed background conditions or differences in elements between the development program analyzed in the 2008 FGEIS and the proposed project would result in significant adverse impacts on historic and cultural resources that were not addressed in the 2008 FGEIS or subsequent technical memoranda.

This chapter provides an assessment of existing and future conditions without and with the proposed project for the project site and a study area surrounding the site, which are described in detail below.

As part of the 2008 FGEIS and the 2001 *Shea Stadium Redevelopment FEIS*, the project site was reviewed for its potential archaeological sensitivity by the New York City Landmarks Preservation Commission (LPC) and the New York State Office of Parks, Recreation, and Historic Preservation (OPRHP) (Special Willets Point District only). LPC and OPRHP have determined that the project site is not sensitive for archaeological resources (see **Appendix B**, “Agency Correspondence”). Thus, this analysis focuses on standing structures only.

PRINCIPAL CONCLUSIONS

This analysis finds that the proposed project would not result in significant adverse impacts related to historic and cultural resources that were not addressed in the 2008 FGEIS or subsequent technical memoranda. Consistent with the findings in the 2008 FGEIS, the development that would occur within the Special Willets Point District during Phase 2 of the proposed project would have a significant adverse effect on the former Empire Millwork Corporation Building.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS analyzed the potential of proposed development within the Special Willets Point District and on Lots B and D on Roosevelt Avenue to have significant adverse effects on historic and cultural resources. The 2008 FGEIS concluded that the Willets Point Development Plan would require the demolition of the former Empire Millwork Corporation Building, which has been determined eligible for listing on the State and National Registers of Historic Places, and thus would have a significant adverse impact on historic resources. The 2008 FGEIS documented substantial challenges inherent in retaining the historic building and incorporating it into the proposed plan. The FGEIS recommended consulting with OPRHP to develop mitigation measures, such as recording the building through a Historic American Buildings Survey (HABS)-level photographic documentation and accompanying narrative.

No other architectural resources were identified within the District or Lots B and D on Roosevelt Avenue.

C. METHODOLOGY

Study areas for architectural resources are determined based on an area of potential effect for construction-period impacts, such as groundborne vibrations, and on the area of potential effect for visual or contextual effects, which is usually a larger area. The study area has been defined as the project site and the area within 400 feet of the project site's boundaries (see **Figure 7-1**). This study area is consistent with 2012 *CEQR Technical Manual* methodology in developing study areas to assess an action's potential impacts on architectural resources, which sets forth that the size of the study area should be directly related to the anticipated extent of the action's impacts.

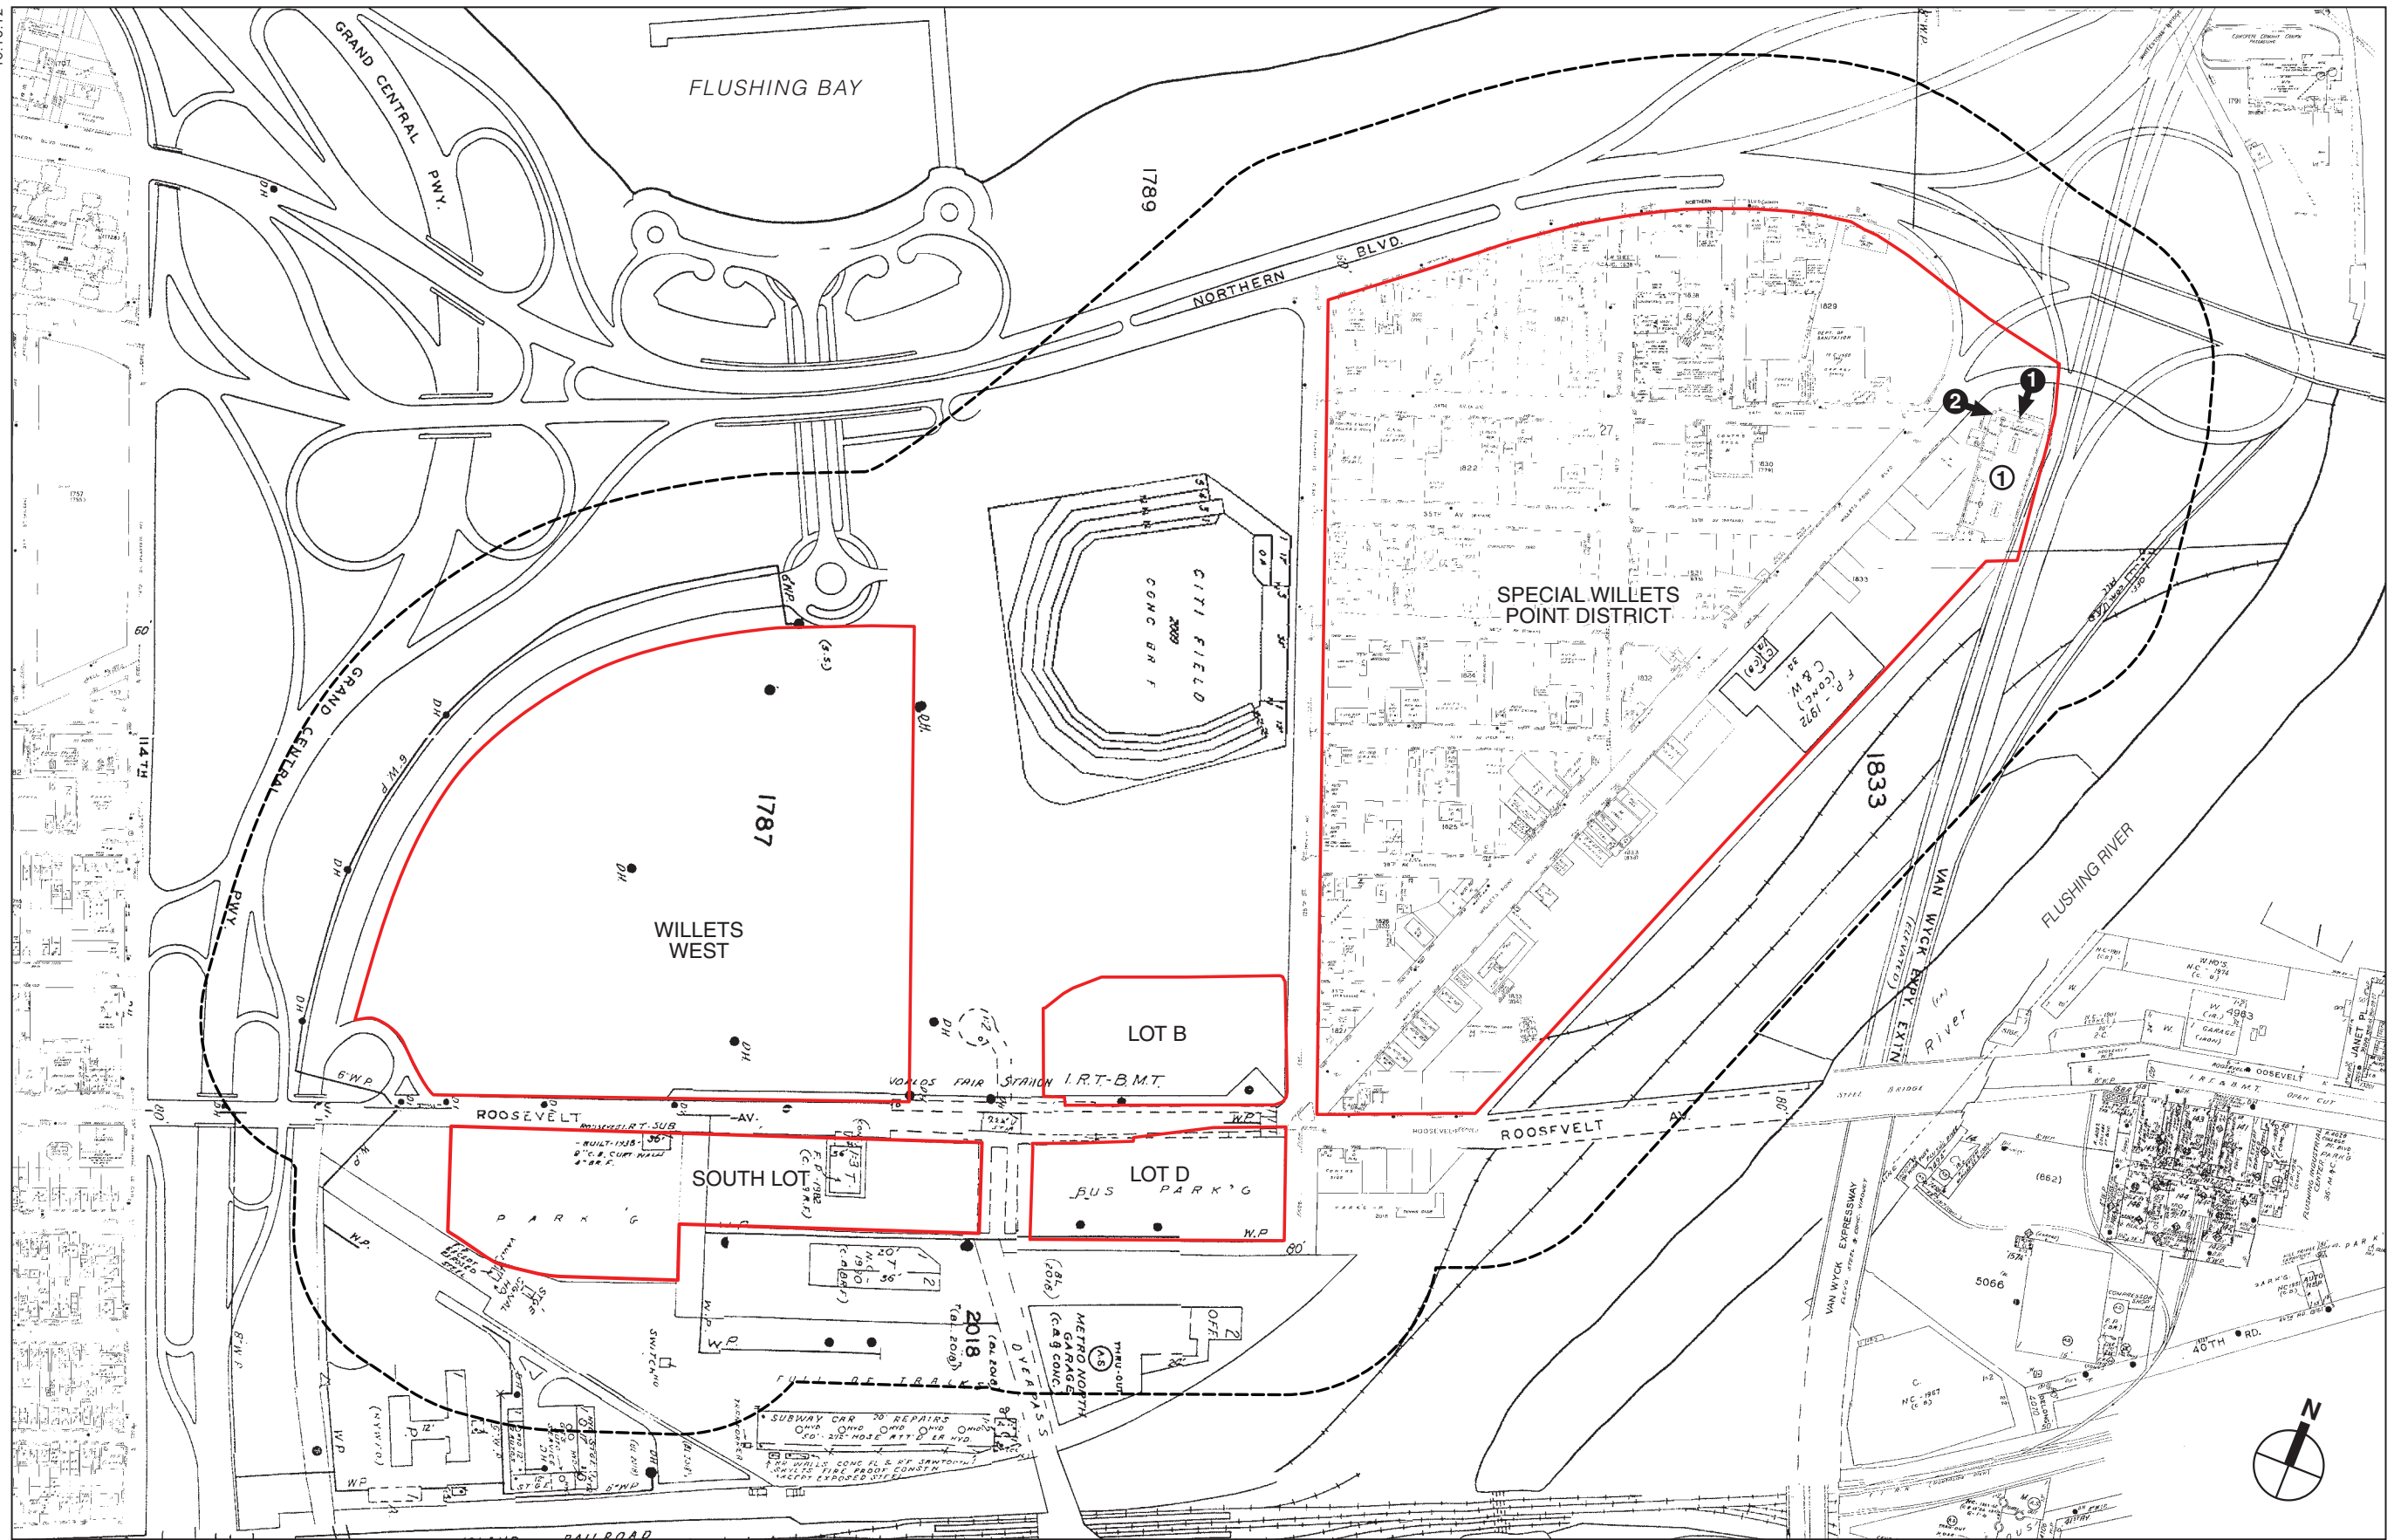

To assess the potential impacts of the proposed project, an inventory of architectural resources in the study area was compiled. In accordance with CEQR guidelines, the inventory includes all officially recognized architectural resources. These resources ("known architectural resources") are defined as National Historic Landmarks (NHLs); properties or districts listed on the State and National Registers of Historic Places (S/NR), or previously determined to be eligible for such listing; New York City Landmarks (NYCLs) and Historic Districts (NYCHDs); and properties that have been considered for designation ("heard") by the New York City Landmarks Preservation Commission (LPC) at a public hearing, calendared for consideration at such a hearing ("pending" NYCLs), or found by LPC to appear eligible for designation.

In addition to identifying known architectural resources, an evaluation of the study area was undertaken to identify any "potential architectural resources"; that is, other buildings in the study area that could warrant recognition as architectural resources (properties that could be eligible for S/NR listing or NYCL designation). Properties were evaluated based on site visits by an architectural historian and the review of prior studies of the study area.

Once the architectural resources in the study area were identified, the proposed project was assessed for its potential to have direct, physical impacts and/or indirect visual or contextual impacts on architectural resources. Direct impacts include demolition of a resource, and alterations to a resource that cause it to become a different visual entity. A resource could also be physically damaged from adjacent construction, either from vibration (i.e., from construction blasting or pile driving), or from falling objects, subsidence, collapse, or damage from construction machinery. Adjacent construction is defined as any construction activity that would occur within 90 feet of an architectural resource, as defined in the New York City Department of Building's (DOC) *Technical Policy and Procedure Notice (TPPN) #10/88*.

Indirect impacts are contextual or visual impacts that could result from project construction or operation. As described in the 2012 *CEQR Technical Manual*, indirect impacts could result from blocking significant public views of a resource; isolating a resource from its setting or relationship to the streetscape; altering the setting of a resource; introducing incompatible visual, audible, or atmospheric elements to a resource's setting; or introducing shadows over a historic landscape or an architectural resource with sun-sensitive features that contribute to that resource's significance (e.g., a church with stained-glass windows).

The setting of each architectural resource, including its visual prominence and significance in publicly accessible views, whether it has sun-sensitive features, and its visual and architectural relationship to other architectural resources, was taken into consideration for this analysis.

D. EXISTING CONDITIONS

PROJECT SITE

The project site is composed of three discrete areas, roughly bounded by Shea Road and Northern Boulevard to the north, the Van Wyck Expressway to the east, the MTA Corona Rail Yard to the south, and Shea Road to the west (see **Figure 7-1**). The three portions of the project site are defined as the Special Willets Point District, Willets West, and Roosevelt Avenue. The Special Willets Point District is the triangular area bounded by 126th Street, Northern Boulevard, and the Van Wyck Expressway. The Willets West portion of the project site is a 30.7-acre section of the surface parking field west-adjacent to CitiField. The Roosevelt Avenue portion of the site consists of three CitiField-related surface parking lots along Roosevelt Avenue, South Lot and Lots B and D.

There are no known or potential architectural resources within the Willets West and Roosevelt Avenue portions of the project site.

The 2008 FGEIS identified one architectural resource within the Special Willets Point District: the former Empire Millwork Corporation Building at 128-150 Willets Point Boulevard (see **Figure 7-2**). As part of the 2008 FGEIS, the structure was determined S/NR-eligible by OPRHP as a significant early 20th century commercial and industrial building.

The former Empire Millwork Corporation Building, built in 1938 prior to the Van Wyck Expressway and facing Flushing Bay, has a large landscaped lawn in front. It was constructed from plans by Sugarman & Berger, Stanford D. Rossin, and Arthur Hamburger. Hamburger, an industrial engineer, was president of Wheeler Engineering Company, which built the building. The building was constructed for the D. Ginsberg and Sons Company, a millwork company which was started in 1921 by Hyman Ginsberg. The company later became the Empire Millwork Corporation and then the Empire National Corporation.

The two-story, Georgian Revival-style building has a symmetrical red brick façade with flanking bays, which terminate with gently curving sections. The front section was originally used as an office space for the company, and the exterior decorations are a reflection of the millwork business. The central bay projects slightly and features a center doorway topped with arched transom windows and a broken pediment. Above the door is a large Palladian window with a circular clock under the central arch. The central bay is topped with a large front gable with a wood denticulated cornice and cornice returns. Small octagonal windows decorate either side of the central entryway. The flanking sections are five bays wide. Each bay has arched wood windows with tracery on the first level and 6-over-6 double-hung wood windows on the upper level. A denticulated cornice line runs the length of the bays. Both bays end with curved sections; these sections have large 12-over-12 double-hung windows separated by double height wood pilasters. The side bays have small, double-hung and octagon-shaped windows. A short parapet runs along the flanking bays and sides. The remainder of the building is a two-story warehouse structure which extends back approximately 300 feet. It has large factory-style, multi-pane glass windows.

There are no other known or potential architectural resources located within the Special Willets Point District portion of the project site.

Former Empire Millwork Corporation Building, front facade 1

Former Empire Millwork Corporation Building, view southeast 2

STUDY AREA

There are no known or potential architectural resources located within the 400-foot study area. A portion of the Olmsted Center in Flushing Meadows-Corona Park falls within the study area boundary. While this one-story modular building was built as the 1964–65 World's Fair Corporation's administrative offices, it is not considered to be a potential architectural resource.

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

PROJECT SITE

Without the proposed project, in all three analysis years it is expected that the former Empire Millwork Corporation Building will continue in its present use.

STUDY AREA

Absent the proposed project, two projects are expected to be built within the study area by 2018. One is a one-story guard/monitoring booth for the industrial site located at 32-11 Harper Street. The second, located at 39-14 114th Street, is development that will contain 23 dwelling units, 18,638 square feet of commercial space, 4,794 square feet of community facility space, and 31 parking spaces. No additional projects are anticipated to be built within the study area by 2028 or 2032. As described above, there are no known or potential architectural resources within the study area.

Changes to the architectural resource identified above or to its setting could occur irrespective of the proposed project. The S/NR-eligible architectural resource could be listed on the Registers, or determined eligible and designated as a NYCL. Future projects could also affect the setting of the architectural resource. It is possible that the architectural resource could deteriorate, or could be restored. In addition, future projects could accidentally damage the architectural resource through adjacent construction.

Historic resources that are listed on the S/NR or that have been found eligible for listing are given a measure of protection under Section 106 of the National Historic Preservation Act from the effects of projects sponsored, assisted, or approved by federal agencies. Although preservation is not mandated, federal agencies must attempt to avoid adverse effects on such resources through a notice, review, and consultation process. Properties listed on the Registers are similarly protected against effects resulting from projects sponsored, assisted, or approved by state agencies under the State Historic Preservation Act. However, private owners of properties eligible for, or even listed on, the Registers using private funds may alter or demolish their properties without such a review process, assuming no state or federal approvals are required. Privately owned properties that are NYCLs and in NYCHDs are protected under the New York City Landmarks Law, which requires LPC review and approval before any alteration or demolition permits can be issued, regardless of whether the project is publicly or privately funded. Publicly owned resources are also subject to review by LPC before the start of a project. However, LPC's role in projects sponsored by other city or state agencies generally is advisory only.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

PROJECT SITE

As described above, there are no architectural resources located within the Willets West or Roosevelt Avenue portions of the project site. Therefore, there would be no impacts to architectural resources from the development of these areas in Phases 1A, 1B, or 2 of the proposed project.

Phases 1A and 1B of the proposed project would not impact, physically or contextually, the former Empire Millwork Corporation Building. The new development that would occur in these phases in the western half of the District would alter the context of this resource, but the new development is anticipated to improve the physical environment and thus surrounding views. Views to the resource from 34th Avenue and Willets Point Boulevard would not be obstructed. The anticipated Van Wyck Expressway ramp configuration—which would be constructed by 2028—would not adversely affect the building.

In Phase 2 of the proposed project, it is anticipated that the former Empire Millwork Corporation Building would be demolished, consistent with the 2008 FGEIS. Demolition of this historic resource would constitute a significant adverse impact on architectural resources.

The development in the District in Phase 2 would be guided by the special district regulations and the Willets Point Urban Renewal Plan (URP) adopted in 2008. One of the key aspects of the special district regulations and the URP is to allow for flexibility of uses and building locations within the District. Retaining the former Empire Millwork Corporation Building would limit this flexibility. In addition, retaining the former Empire Millwork Corporation Building would be challenging from a site grading and engineering perspective. The District is below the Federal Emergency Management Agency (FEMA) 100-year floodplain level of 14 feet above mean sea level (AMSL), and up to seven feet of fill would be required in some locations to grade and raise the entire District to an elevation of between 14 and 17 feet AMSL. If the City were to provide new infrastructure—including new roadways, sidewalks, and storm and sanitary sewer lines—at the existing grade, potential future development could be subject to flooding on the lower floors. As such, the City plans to raise the District and require that any new development be raised above the 100-year floodplain level. The site of the former Empire Millwork Corporation Building would require up to 3.4 feet of fill to conform to the future grade of the District.

As the former Empire Millwork Corporation Building is at the District's existing grade and located near the Flushing Bay inlet, it is presumed that it is subject to flooding on the lower floors and would remain so in the future without the proposed project. If the former Empire Millwork Corporation Building were not raised it would be significantly more vulnerable to flooding, both because it is below AMSL, and because the surrounding topography would be raised, directing water runoff into lower areas. Raising the grade in a majority of the District while maintaining the existing grade on the former Empire Millwork Corporation Building site would require special engineering measures to protect the building during site preparation and construction to prevent future flooding on the site, and to visually and functionally integrate the building with the rest of the District despite the differences in grade.

In a letter dated May 30, 2008, OPRHP stated that the demolition of the former Empire Millwork Corporation Building would constitute an adverse impact, and that all alternatives to demolition have not been explored. The substantial challenges inherent in retaining the former Empire Millwork Corporation Building as part of the proposed project are detailed above.

Willets Point Development

Furthermore, retention of the structure would not advance the goals and objectives of the approved Willets Point Development Plan, including the improvement of environmental conditions and the development of affordable housing, community facilities, and public open space.

A developer for Phase 2 has not yet been selected, and the Queens Development Group, LLC (QDG) may or may not be selected as the designated developer for Phase 2. Before the development of Phase 2, the selected developer will consult with OPRHP and LPC to evaluate any remaining potential alternatives to demolition. If none are identified, measures to fully or partially mitigate this adverse impact have been developed, as discussed in Chapter 21, "Mitigation." As discussed in the 2008 FGEIS, these would include consultation with OPRHP to develop mitigation measures, such as recording the building through a HABS-level photographic documentation and accompanying narrative.

STUDY AREA

As there are no architectural resources in the study area, there would be no impacts on such resources in the future with the proposed project.

In summary, this analysis finds that the proposed project would not result in any significant adverse impacts related to historic and cultural resources that were not addressed in the 2008 FGEIS. *

A. INTRODUCTION

This chapter assesses the potential of the proposed project to affect urban design and visual resources. The analysis updates changes to the proposed project and background conditions since the 2008 Final Generic Environmental Impact Statement (FGEIS) and assesses whether any changed background conditions or differences in elements between the development program analyzed in the 2008 FGEIS and the proposed project would result in significant adverse impacts on urban design and visual resources that were not addressed in the 2008 FGEIS.

Under the 2012 *City Environmental Quality Review (CEQR) Technical Manual*, urban design is defined as the totality of components that may affect a pedestrian's experience of public space. These components include streets, buildings, visual resources, open spaces, natural resources, and wind. An urban design assessment under CEQR must consider whether and how a project may change the experience of a pedestrian in a project area. The *CEQR Technical Manual* guidelines recommend the preparation of a preliminary assessment of urban design and visual resources, followed by a detailed analysis if warranted based on the conclusions of the preliminary assessment. The analysis provided below addresses urban design characteristics and visual resources for existing conditions, the future without the proposed actions, and the probable impacts of the proposed project.

PRINCIPAL CONCLUSIONS

This analysis finds that the proposed project would not result in significant adverse impacts related to urban design and visual resources that were not addressed in the 2008 FGEIS. Overall, this analysis concludes that the proposed project would not have any significant adverse impacts related to urban design and visual resources, consistent with the findings of the 2008 FGEIS and subsequent technical memoranda.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS concluded that the Willets Point Development Plan would add new uses and vitality to the site and would greatly improve the appearance of the Special Willets Point District. While the Plan would significantly alter the urban design of the District, it would ultimately have a beneficial impact on the overall appearance and feel of the District. The Plan would transform the underdeveloped District into a vibrant, mixed-use urban environment. The buildings that would result from the Plan were found to be cohesive in design and varied in use to create a new destination and entertainment location. The Plan also would have integrated the District into the surrounding area by creating a new pedestrian-scaled street network with wide connector streets as well as smaller, retail and residential streets. In addition, the Plan would have added new publicly accessible open spaces to the District.

The 2008 FGEIS concluded that the new mixed-use development resulting from the Plan would have increased the vitality of the District; increased pedestrian traffic to the District and the surrounding area; and improved the appearance of the District by providing new streets and streetscape elements, such as street trees and lighting. The new buildings would be set back at a consistent distance and built to a similar height to create new, continuous streetwalls. The Plan also would not adversely affect any visual resources in the surrounding area, including Flushing Bay, the Flushing Bay Promenade, Flushing Meadows-Corona Park, and the 1964–65 World’s Fair structures.

C. PRELIMINARY ASSESSMENT

Based on the *CEQR Technical Manual*, a preliminary assessment of urban design and visual resources is appropriate when there is the potential for a pedestrian to observe, from the street level, a physical alteration beyond that allowed by existing zoning. Examples include projects that permit the modification of yard, height, and setback requirements, and projects that result in an increase in built floor area beyond what would be allowed “as of right” in the future without the proposed actions.

To facilitate the redevelopment of the project site, several discretionary actions would be required, including a zoning special permit to allow surface parking/open and enclosed privately-operated recreation uses for Phase 1A within the Special Willets Point District. While the proposed actions do not constitute an upzoning, they would be expected to result in physical alterations within the District beyond those allowed by existing zoning, and thus would meet the threshold for a preliminary assessment of urban design and visual resources.

The *CEQR Technical Manual* guidelines state that if the preliminary assessment shows that changes to the pedestrian environment are sufficiently significant to require greater explanation and further study, then a detailed analysis is appropriate. Examples include projects that would potentially obstruct view corridors, compete with icons in the skyline, or make substantial alterations to the streetscape of a neighborhood by noticeably changing the scale of buildings. Detailed analyses also are generally appropriate for areawide rezonings that include an increase in permitted floor area or changes in height and setback requirements, large-scale general developments (LSGDs), or projects that would result in substantial changes to the built environment of a historic district or components of a historic building that contribute to the resource’s historic significance. Conditions that merit consideration for further analysis of visual resources include when the project partially or totally blocks a view corridor or a natural or built visual resource that is rare in the area or considered a defining feature of the neighborhood; or when the project changes urban design features so that the context of a natural or built visual resource is altered (i.e., if the project alters the street grid so that the approach to the resource changes; if the project changes the scale of surrounding buildings so that the context changes; or if the project removes lawns or other open areas that serve as a setting for the resource).

The proposed project would involve changes to Willets West and Roosevelt Avenue portions of the project site, which were not previously analyzed as part of the 2008 FGEIS or subsequent technical memoranda. These changes would noticeably alter the scale of buildings on these portions of the project site, compared to the future without the proposed project. These portions of the project site would go from being developed with surface parking lots to being occupied by structures ranging in height from approximately 63 to 105 feet tall. Therefore, the proposed project would meet the threshold for a detailed assessment of urban design and visual resources. This analysis is provided below.

D. METHODOLOGY

This analysis has been prepared in accordance with CEQR procedures and follows the guidelines of the 2012 *CEQR Technical Manual*.

As defined in the *CEQR Technical Manual*, urban design is the totality of components that may affect a pedestrian's experience of public space. This detailed assessment considers the effects of the proposed actions on the experience of a pedestrian in the study area. The assessment focuses on those project elements that have the potential to alter the built environment, or urban design, of the project area, which is collectively formed by the following components:

- Streets—the arrangement and orientation of streets define location, flow of activity, street views, and create blocks on which buildings and open spaces are arranged. Other elements including sidewalks, plantings, street lights, curb cuts, and street furniture also contribute to an area's streetscape.
- Buildings—a building's size, shape, setbacks, pedestrian and vehicular entrances, lot coverage and orientation to the street are important urban design components that define the appearance of the built environment.
- Visual Resources—visual resources include significant natural or built features, including important views corridors, public parks, landmarks structures or districts, or otherwise distinct buildings.
- Open Space—open space includes public and private areas that do not include structures, including parks and other landscaped areas, cemeteries, and parking lots.
- Natural Features—natural features include vegetation and geologic and aquatic features that are natural to the area.

The *CEQR Technical Manual* recommends an analysis of pedestrian wind conditions for projects that would result in the construction of large buildings at locations that experience high wind conditions (such as along the waterfront, or other location where winds from the waterfront are not attenuated by buildings or natural features), which may result in an exacerbation of wind conditions due to “channelization” or “downwash” effects that may affect pedestrian safety. While the project site is near the Flushing Bay waterfront, the proposed buildings would be limited in height by Federal Aviation Administration regulations, due to the proximity of the LaGuardia Airport. Furthermore, the project site is separated from the waterfront by elevated roadways, which reduce local wind conditions. Therefore, a pedestrian wind conditions analysis has not been prepared.

The study area for the urban design and visual resources analysis is consistent with that of the primary study area for the analysis of land use, zoning and public policy. This study area extends roughly from Flushing Bay to the north; Linden Place, Parsons Boulevard, and College Point Boulevard to the east; United Nations Avenue North within Flushing Meadows-Corona Park to the south; and 108th and 111th Streets on the west (see **Figure 8-1**).

As detailed in the Staged Acquisition Alternative of the FGEIS and subsequent technical memoranda, since development would occur more incrementally in the District under the proposed project, and there would not be an open space area buffering eastern portions of the Phase 1A and 1B development from the industrial uses that would remain in the eastern portions of the District to be developed later (as previously analyzed), for Phases 1A and 1B the Supplemental Environmental Impact Statement (SEIS) will consider the contrast between the redeveloped portion of the District and the area that would remain largely industrial in nature.

Study Area Map

Figure 8-1

E. EXISTING CONDITIONS

URBAN DESIGN

PROJECT SITE

The project site is composed of three discrete areas, roughly bounded by Shea Road and Northern Boulevard to the north, the Van Wyck Expressway to the east, the Metropolitan Transportation Authority (MTA) Corona Rail Yard to the south, and Shea Road to the west (see **Figures 8-1** and **8-2**). The three portions of the project site are defined as the Special Willets Point District, Willets West, and Roosevelt Avenue.

The Special Willets Point District is a triangular area roughly bounded by 126th Street to the west, Northern Boulevard to the north, the Van Wyck Expressway to the east, and Roosevelt Avenue to the south. This District is approximately 61.4 acres in size. The District is partially developed in a street grid, with 34th through 39th Avenues running east-west, and with 127th Street running north-south between Northern Boulevard and 37th Avenue. Short north-south streets—126th Place, 127th Street, and 127th Place—extend between Northern Boulevard and 34th Avenue. Willets Point Boulevard is the main thoroughfare through the District. Starting at 126th Street, it runs on a diagonal that extends northeast to the entrance of the Van Wyck Expressway. There are no streets south of Willets Point Boulevard in the District. 126th Street forms the western boundary of the District, running parallel to 127th Street and extending between Northern Boulevard and Roosevelt Avenue.

Due to the diagonal trajectory of Willets Point Boulevard and the curve of Northern Boulevard, the majority of the 14 blocks within the District are irregular in shape. The blocks on 34th Avenue curve to conform to the shape of Northern Boulevard. Triangular and trapezoidal blocks are created by Willets Point Boulevard's diagonal path. The three blocks located between 34th and 37th Avenues, and 126th and 127th Streets are the only rectangular-shaped blocks in the District. The majority of the buildings within the District are small, temporary metal structures, metal Quonset huts, and brick buildings with small footprints and large, projecting advertising signs (see Views 1-3 of **Figures 8-3** and **8-4**). These structures house automotive repair shops, wholesale auto parts stores, and other auto-related uses. Most of the buildings in the District are attached or located close together. In contrast, in the northeast section of the District there are a number of freestanding buildings that are larger and boxier in form. These include the Tully Construction site, which contains a three-story, boxy red brick building and is surrounded by a metal chain-link fence topped with barbed wire. Large trucks and other manufacturing equipment are stored on the site. Another notable building in this portion of the District is the historic former Empire Millwork Corporation Building (see Chapter 7, "Historic and Cultural Resources"). This two-story, Georgian Revival-style red brick building is located near the intersection of Willets Point Boulevard and the Van Wyck Expressway (see View 4 of **Figure 8-4**).

The streetscape of the District is industrial in character. Most of the streets are flanked by paved sidewalks, which are in poor condition. The sidewalks have wide curb cuts and are only slightly elevated; in some parts, the sidewalks are almost flush with the streets. The sidewalks are also used for car parking, auto parts storage, and waste storage. The streets in the District also are in various states of disrepair. Most are partially paved and riddled with potholes. The only streets with designated or marked traffic lanes are 126th Street and Willets Point Boulevard. There are few sidewalk crossings or stop signs. Mature sycamore trees line 126th Street; they are the only

Special Willets Point District, view north on Willets Point Boulevard

Former Empire Millwork Corporation Building **4**

Views of Special Willets Point District

vegetation in the District. Streetscape elements are limited to cobra-head lights and utility poles with wires strung between them; the streets lack traditional streetscape elements such as trees, fire hydrants, and other street furniture. In some areas, the streetscape is broken up by lots surrounded by chain-link fencing or sheets of corrugated metal, which are used for parking and storage of used cars and other auto parts.

The boundaries of the District portion of the project site are the same as the Special Willets Point District—a special zoning district that is coterminous with a C4-4 zoning district—and the Willets Point Urban Renewal Plan (URP) (see Figure 2-2 in Chapter 2, “Land Use, Zoning and Public Policy”). The District was created in 2008 to allow for the redevelopment of this area consistent with the Willets Point Development Plan. Within the District, the zoning allows a range of maximum FARs, from 2.0 to 5.0. To create an appropriate scale and density within its boundaries, the special zoning district regulates a number of urban design elements, including the number of intersections along 126th Street, building heights and setbacks, street hierarchies, streetscape design, and basic site planning and design provisions. The URP, also adopted in 2008, established maximum square footage development envelopes in accordance with the City’s redevelopment goals. The overall maximum permitted floor area in the District was defined as 8.94 million square feet of zoning floor area (zsf), with maximum permitted floor areas for residential and commercial uses (5,850,000 zsf of residential use, 3,160,000 zsf of commercial use). The URP, as well as the special district regulations, also requires the creation of a minimum of eight acres of open space in the District and a minimum 650-seat school.

The Willets West portion of the project site is an approximately 30.7-acre section of the paved surface parking field west-adjacent to CitiField. This portion of the site is mapped as parkland; however, it does not function as open space. The land was occupied by Shea Stadium and associated parking and circulation space until it was replaced by CitiField in 2009, and it is now occupied exclusively by surface parking (see Views 5 and 6 of **Figure 8-5**). The area is lit by tall floodlights and there are traffic islands within and around the perimeter of the surface parking area, which are currently planted with trees. There are no structures on this portion of the project site.

The Roosevelt Avenue portion of the site consists of three CitiField-related, paved surface parking lots along Roosevelt Avenue, South Lot and Lots B and D (see Views 7 and 8 of **Figure 8-6**). The South Lot and Lot D are located between Roosevelt Avenue and the MTA Corona Rail Yard, and are separated by the elevated Passerelle Ramp, which extends south from the Mets-Willets Point subway station and comes to grade adjacent to the USTA National Tennis Center. There are two small station-related structures fronting on Roosevelt Avenue around the South Lot, but these are not included in this portion of the project site.

The South Lot and Lot D are collectively approximately 12.1 acres in size. Lot B is located on the north side of Roosevelt Avenue, west of 126th Street; this paved surface parking lot currently serves as VIP/ADA parking for CitiField (see View 9 of Figure 9-7). Lot B is approximately 4.7 acres in size. The parking areas each include a small number of trees at the site perimeter and are lit by tall floodlights. Lot B is surrounded by a decorative metal fence; the South Lot and Lot D are surrounded by chain link fencing. As with Willets West, the South Lot and Lots D and B are mapped as parkland but do not function as open space. There are no structures on this portion of the project site, except for small temporary structures related to the parking use.

Overall, the project site has no natural features, and its topography is relatively flat.

STUDY AREA

As with the project site, the study area comprises several discrete areas. These are: the remaining portions of the Willets Point peninsula that lie outside the boundaries of the District; Flushing Meadows-Corona Park; to the east, Downtown Flushing and the greater Flushing area, which are separated from the Willets Point peninsula by the Flushing River; and to the west of the project site and the western boundary of Flushing Meadows-Corona Park, portions of the neighborhood of Corona.

Directly southeast of the District on the Willets Point peninsula, along the Flushing River waterfront, is a large undeveloped MTA property that is currently in use by a construction and demolition debris recycling operation. The site contains shipping containers, heavy equipment, and piles of aggregate materials.

Directly north of the District on the Willets Point peninsula is a New York City Department of Transportation (NYCDOT) maintenance and repair facility. This site contains seven freestanding buildings, one and two stories in height and constructed of brick and steel with minimal exterior details; in addition, the site has a large paved area used for parking and vehicle storage. Most of the site is surrounded by a metal chain-link fence. Between Northern Boulevard and the Van Wyck Expressway is an asphalt plant. This industrial site is surrounded by a high concrete wall and jersey barriers. The site includes a one- and two-story metal and concrete building, a boxy one-story metal storage building, and a large industrial structure with metal silos and connecting ramps. The site is paved, with piles of asphalt and heavy industrial equipment located across it. The MTA, NYCDOT, and asphalt plant properties are all zoned M3-1, which allows development of up to 2.0 FAR.

Separating the District from the NYCDOT and asphalt plant sites is Northern Boulevard and the elevated connector between the Van Wyck Expressway—which runs along the eastern edge of the District—and the Grand Central Parkway. This elevated connector, approximately 40 feet in height, carries traffic over Northern Boulevard and is also supported by tall T-shaped concrete piers (see View 10 of **Figure 8-7**). Near the District, Northern Boulevard has numerous exit and entrance ramps. Streetscape features on Northern Boulevard and the Van Wyck Expressway include tall highway signs, tall metal fencing, cobra-head lighting fixtures, and low guardrails. The area under the elevated connector is used for car parking. There is little pedestrian activity in this portion of the study area.

The portions of the 900-acre Flushing Meadows-Corona Park that fall within the study area extend north to Flushing Bay, west to 111th and 114th Streets, south to the southern boundary of the USTA NTC site, and east to Van Wyck Expressway. The park area between the Willets West and District portions of the project site is occupied by CitiField, the baseball stadium for the Mets that opened in 2009. The stadium is clad in red brick, and its principal entrance is oriented toward Roosevelt Avenue; this southwest corner of the building is rounded, evoking Ebbets Field (see View 11 of **Figure 8-8**). A paved plaza with landscaping links the stadium with the stairway leading to the elevated Mets-Willets Point subway station. The elevated train line runs above Roosevelt Avenue on a steel viaduct structure and spans the entire width of Roosevelt Avenue, casting the street in shadow (see View 12 of **Figure 8-8**). The station platforms are constructed in concrete and bordered by corrugated metal walls with overhangs that partially shade the platforms.

To the north of Northern Boulevard is the Flushing Bay Promenade, which winds along Flushing Bay for approximately 1.4 miles from LaGuardia Airport to the Willets Point peninsula. The

Views of Project Site

Figure 8-7

CitiField, view from No. 7 train platform 11

View east on Roosevelt Avenue near Grand Central Parkway 12

Views of Study Area

promenade has decorative paving and contains many sitting areas, with a landscaped buffer between the walkway and the Northern Boulevard access road; it provides access to the World's Fair Marina and a restaurant located northeast of CitiField (see View 13 of **Figure 8-9**). There are more than 1,000 parking spaces located to the east and west of the marina, which are also available for parking on Mets game days. The marina hosts small recreational boats; ferries and other larger vessels dock at the World's Fair Pier. When not in use, public access to the pier is blocked by a chain-link gate. The Candela Structures, two open-air, expressionistic modern structures that provide shade and originally served as bus shelters for the 1964–65 World's Fair are located along the Promenade just north of CitiField.

Directly south of the Roosevelt Avenue portion of the project site is the 23-acre MTA Corona Rail Yard. The rail yard, which is not part of Flushing Meadows-Corona Park and is zoned M1-1, is primarily used for the storage and maintenance of subway trains, but also includes surface parking areas and a few brick utilitarian structures (see View 14 of **Figure 8-9**). The rail yard is lighted by tall posts with flood lights and bounded by chain link fencing. There is a Long Island Rail Road (LIRR) Mets-Willets Point station within the rail yard, which operates on CitiField game days and during the US Open.

The New York City Transit (NYCT) Casey Stengel Bus Depot is adjacent to the east of the MTA Corona Rail Yard. The bus depot comprises two buildings located on a large lot south of Roosevelt Avenue and west of 126th Street. These long, narrow buildings are two and three stories in height, with large footprints, and are clad in alternating bands of light and dark concrete (View 15 of **Figure 8-10**).

The elevated No. 7 train station (and the LIRR station when operational) is accessed by the Passerelle Ramp, a pedestrian bridge which extends above the rail yard and connects the station with Flushing Meadows-Corona Park. The ramp is an elevated boardwalk-style structure with low metal railings and reproduction gaslights (see View 16 of **Figure 8-10**). The Passerelle Building, which consists of two tan brick, one-story pavilions separated by a central ramp, comprises the southern end of the Passerelle ramp. The Passerelle Building contains offices and support facilities for the park. The terrace area on the roof of the Passerelle Building, which is covered by fixed canopies, originally provided a viewing area from which visitors to the 1964–65 World's Fair could look across the fairgrounds. The entrance to Flushing Meadows-Corona Park off the Passerelle Ramp is surrounded by flagposts and has a decorative pavement, including mosaics depicting significant scenes and structures from the World's Fairs.

To the west of the rail yard is the Olmsted Center, a one-story modular building built as the 1964–65 World's Fair Corporation's administrative offices that currently contains offices for the design and construction supervision divisions of the New York City Department of Parks and Recreation (DPR) (see View 17 of **Figure 8-11**). Meridian Road is directly south of the rail yard; it provides access to various uses within the park, and the USTA NTC.

The USTA NTC site includes surface parking lots at the northwest and northeast corners of the site; three stadiums along the northern side of the site, decreasing in size from west to east; surface tournament courts along the western and southern edges of the site, some of which have bleacher-style seating; and a smaller stadium and the ±245,000 gross square foot (gsf), 60-foot-tall Indoor Training Center at the southeast corner of the site (see Views 18 and 19 of **Figures 8-11** and **8-12**). The stadiums on the site include, from west to east, the ±362,000-gsf, 120-foot-tall Arthur Ashe Stadium; Louis Armstrong Stadium; and the Grandstand Stadium (both of which are approximately 70 feet tall and collectively comprise approximately 117,000-gsf of enclosed space, approximately 280,000-gsf total). There is a tennis bubble at the northwest

View of Flushing Meadows-Corona Park

Figure 8-12

corner of the site. The project site also includes food, beverage, and retail kiosks, temporary trailers for broadcast use during the US Open, and pedestrian plazas, including South Plaza and the Food Village. South Plaza serves as the focal point of the site during the US Open, and contains two fountains, seating, and retail/informational kiosks. East of South Plaza is the Food Village, which contains tables and seating, and kiosks for food sales during the US Open. Trees, landscaping, and seating are found throughout the site. Loading dock entrances are located at the rear (north) side of the site along Meridian Road and to the southeast along Path of the Americas. The perimeter of the USTA NTC site is mostly defined by chain link fencing, some of which is screened with hedges (and vinyl wind screening during the US Open).

An overpass for United Nations Avenue North provides vehicular and pedestrian access between the east and west sides of Flushing Meadows-Corona Park, which are separated by the Grand Central Parkway. East of the Grand Central Parkway, the pedestrian pathways in Flushing Meadows-Corona Park generally have a geometric, Beaux-Arts plan composed of main spokes radiating out from a central point, the location of the Unisphere just south of the study area (see View 20 of **Figure 8-12**). West of the Grand Central Parkway, the plan of Flushing Meadows-Corona Park is less geometric. Pedestrian pathways wind around the major park uses in this area, which within the study area boundaries include the New York Hall of Science. The original Hall of Science structure is an undulating form composed of precast concrete panels with stained glass; subsequent additions have added a new rotunda entrance and other elements (see View 21 of **Figure 8-13**). Surrounding the Hall of Science is a playground, sculpture, and Mercury-Atlas and Gemini-Titan rockets. There is a large (500-space) parking lot adjacent to the museum.

East of the Passerelle Ramp, the park contains a pitch and putt golf center, tennis courts, playgrounds, playing fields, broad lawn areas, Industry Pond, and trees, pathways, and sitting areas. The Flushing Meadows-Corona Park Pool and Rink is also located in this area. Built in 2008, the structure has curtain wall facades and 130-foot-high twin masts that act as the structural anchor to hold the cable-stayed roof (see View 22 of **Figure 8-13**). At the far-east side of the park south of Roosevelt Avenue and near the Van Wyck Expressway is the Ground Crews Building, a one-story concrete structure that is used as offices and storage for park employees. There is perpendicular street parking adjacent to the tennis courts along Meridian Road east of the Passerelle Ramp, but no sidewalks or pedestrian paths along this portion of the street. Because of the narrow sidewalks near the USTA NTC and lack of pedestrian paths or sidewalks elsewhere, there is little pedestrian traffic along Meridian Road within the study area. The topography within the park is generally flat, with some gentle rises and falls, particularly surrounding the Grand Central Parkway. Within the Flushing Meadows-Corona Park portion of the study area, there are few non-parkland streets or regular city blocks. The streets within the park are winding and landscaped. In some areas there are narrow landscaped medians with tall trees.

East of the elevated Van Wyck Expressway, the Flushing River is traversed by the Roosevelt Avenue Bridge—a single-truss bridge supported by large square piers and surrounded by a high metal fence—as well as by bridges carrying Northern Boulevard and the Whitestone/Van Wyck Expressway. College Point Boulevard, which runs north-south, is the major thoroughfare east of the Flushing River. The portion of the study area between College Point Boulevard and the Flushing River is characterized by large, irregularly shaped parcels and large-footprint, low-scale industrial and commercial structures, including a Home Depot with a large surface parking lot, an asphalt plant, and a lumberyard and processing site. The most prominent buildings on College Point Boulevard are a U-Haul storage facility near 36th Road and the new SkyView Parc mixed use development (see Views 23 and 24 of **Figure 8-14**). The U-Haul structure is a T-

SkyView Parc, view north on College Point Boulevard 24

Study Area Views from College Point Boulevard

shaped concrete building, five stories in height and topped with a two-story, square tower. Capped by a cupola, the tower has a clock on each face. SkyView Parc/SkyView Center, just south of Roosevelt Avenue, has two 18-story towers rising above a large footprint. Along the east side of College Point Boulevard, the buildings are built to the lot line and form a fairly consistent streetwall. College Point Boulevard and the surrounding streets are urban and industrial in character; the sidewalks are wide, with numerous curb cuts. The east side streetscape consists of large industrial buildings, built to the street line and interspersed with large paved parking lots. Along the west side of College Point Boulevard, breaks in the streetscape occur with recessed building entrances and buildings with loading docks set back from the sidewalk line. East of College Point Boulevard are smaller, one-way streets that generally run perpendicular to College Point Boulevard, except north of the Whitestone Expressway. The street grid in this area is discontinuous, creating mostly rectangular but irregularly sized blocks.

East of the College Point Boulevard area is Downtown Flushing. The urban design of already-dense Downtown Flushing has been changing in recent years, as more high-density residential and large-scale mixed-use developments have been constructed or are planned throughout the area. Two large mixed-use development projects, Queens Crossing (recently completed) and Flushing Commons (planned), will be located between Main and Union Streets, north of 39th Avenue. This area is very densely developed, with most buildings occupying most of their lot and extending to the street line (see Views 25 and 26 of **Figure 8-15**). Most of this area's residential uses are located east of Union Street and include 6- to 10-story apartment buildings and three-story rowhouses. The New York City Housing Authority (NYCHA) Bland Houses are located at the southeast corner of Roosevelt Avenue and College Point Boulevard. The Bland Houses complex comprises five irregularly shaped, 10-story unornamented red brick buildings surrounded by 1.7 acres of publicly accessible open space, with amenities such as basketball courts, playground equipment, walkways, and benches. This open space and the approximately half-acre Bland Park are the only publicly accessible open spaces in this portion of the study area. Most streets in the area are lined with retail. The downtown Flushing area includes several surface parking lots, including most prominently Municipal Lot No. 1, located between Union Street, 138th Street, and 37th and 39th Avenues. Municipal Lot No. 1 contains approximately 1,020 public parking spaces, and is the site of the proposed mixed-use development known as Flushing Commons. Several of the area's main community facilities are located close to one another on Northern Avenue, including the Flushing Armory, Friends Meeting House, and Flushing High School; these are also all historic resources. The No. 7 subway line has a terminal station in Downtown Flushing, at Roosevelt Avenue and Main Street.

The study area west of Flushing Meadows-Corona Park includes a portion of the neighborhood of North Corona. The buildings in this area are generally two- and three-story detached, semi-detached and attached houses, and small apartment buildings of up to three stories (see Views 27 and 28 of **Figure 8-16**). They set back slightly from the lot line and are faced in brick or aluminum/vinyl siding. Neighborhood retail uses are primarily located along Roosevelt Avenue; other non-residential uses include gas stations, car washes, and vehicle repair shops. A few auto-related uses are located on Northern Boulevard. Some light manufacturing uses are located on 111th Street between Northern Boulevard and Astoria Boulevard, including a live chicken wholesale warehouse and storage warehouse. A construction material distribution warehouse and a few auto-related uses are also located on Roosevelt Avenue. Hinton Park is located directly west of Flushing Meadows-Corona Park and the Grand Central Expressway; it is a 3.7-

Figure 8-16

acre park that stretches from 34th to 37th Avenues between 113th and 114th Streets and features game tables, benches, baseball diamonds, and play areas (see View 29 of **Figure 8-17**).

This portion of the study area contains rectangular blocks and thus a regular street pattern, with one-way traffic. The blocks south of 37th Avenue are generally oriented east-west; the blocks to the north are generally oriented north-south. Power lines run overhead and sidewalks are lined with street trees. While buildings in this area are generally older, there are also some new structures in the area, including the 8-story, dark brick Holiday Inn just south of Hinton Park. The right-of-way for the LIRR Port Washington Line runs parallel with 44th Avenue in this portion of the study area, before it extends east into Flushing Meadows-Corona Park and then into Flushing, running just north of 41st Avenue (see View 30 of **Figure 8-17**).

VISUAL RESOURCES

PROJECT SITE

There are no visual resources within the District portion of the project site, nor are any visible from its sidewalks and streets. Views to the west are blocked by CitiField. Natural features surrounding the District, including those in Flushing Meadows-Corona Park, Flushing Bay, and the Flushing River, are not visually accessible primarily due to the elevated transportation structures to the north, south, and east of the District.

There are no visual resources within the Willets West or Roosevelt Avenue portions of the project site. The elevated viaduct for the No. 7 train and the MTA Corona Rail Yard create a visual and physical barrier between these portions of the project site and areas to the south. Views to the north are limited by Northern Boulevard and the elevated Grand Central Parkway connector. The Grand Central Parkway, which runs in a north-south direction through the study area, also creates a visual and physical barrier between the project site and areas to the west, as the Flushing River and Van Wyck Expressway do to the east.

STUDY AREA

There are a number of visual resources in or visible from the study area, including: the landscaping, trees, and open lawns of Flushing Meadows-Corona Park; its structures and sculpture associated with the 1964–65 World’s Fair, most prominently the Unisphere and the multi-level towers of the New York State Pavilion; and waterfront views from the Flushing Bay Promenade.

Views from the Promenade are long across Flushing Bay (see View 31 of **Figure 8-18**). To the north, these views mostly contain the commercial and industrial buildings of the College Point Industrial Park; LaGuardia Airport and the Whitestone Bridge are also visible in the distance. Views to the south from the Promenade include CitiField, above the elevated Grand Central Parkway connector.

The Unisphere and the New York State Pavilion are visible from a variety of vantage points within the study area. Though they have limited visibility except from nearby locations, the various sculptures within Flushing Meadows-Corona Park also contribute to its visual environment and are considered to be visual resources. The long allees of mature trees along Flushing Meadow Corona Park’s main axes—including the Path of the Americas between the Unisphere and the park entrance at the Passarelle Ramp, the Avenue of Commerce leading south from this park entrance, and the Herbert Hoover and Dwight Eisenhower Promenades between

Hinton Park, view north from 37th Avenue **29**

Views of Study Area - Corona

View north from Flushing Bay Promenade 31

Avenue of the Americas, view south in Flushing Meadows-Corona Park 32

Views of Study Area

Figure 8-18

the Unisphere and Industry Pond—are also considered to be visual resources (see View 32 of **Figure 8-18**). Views from the Passarelle Ramp itself are long and include the project site as well as most of the study area; however, the primary views from the ramp are south toward Flushing Meadows-Corona Park, rather than north to the project site. Visual resources that can be seen from the ramp include the landscaping of Flushing Meadows-Corona Park, the Unisphere, and the New York State Pavilion. Arthur Ashe Stadium and CitiField are also notable elements in views from the Passarelle Ramp as well as elsewhere in the study area (see Views 33-35 of **Figures 8-19** and **8-20**).

The perspectives of the No. 7 train itself and the elevated roadways surrounding the project site provide fleeting views of the resources noted above.

The twin masts of the Flushing Meadows-Corona Park Pool and Rink are also notable in fleeting views from the Van Wyck Expressway, as well as from nearby portions of the park. In Downtown Flushing, several historic resources located close together on Northern Boulevard are visual resources—specifically the Friends Meeting House, the Flushing Municipal Courthouse, and Flushing High School—but these can only be viewed from immediately adjacent streets.

F. THE FUTURE WITHOUT THE PROPOSED PROJECT

PROJECT SITE

As described in Chapter 1, “Project Description,” for the purposes of a conservative analysis, this EIS assumes that no changes occur on the project site in the future without the proposed project for the three analysis years (2018, 2028, and 2032). Therefore, no changes are anticipated to the site’s urban design or views to surrounding visual resources.

STUDY AREA

In the future without the proposed project in 2018, 2028, and 2032, the remainder of the Willets Point peninsula, including the undeveloped MTA property to the east of the District, is also expected to remain unchanged.

As described in detail in Chapter 2, “Land Use, Zoning, and Public Policy,” and mapped on Figure 2-4, approximately 37 development projects are either under construction or proposed for the study area, all but two of which are anticipated to be complete by 2018. Most of these projects are within the Flushing portion of the study area, including several large-scale, mixed-use redevelopments along the waterfront; however, there is also a cluster of projects in North Corona between Astoria and Northern Boulevards related to the recent rezoning of this area. If developed, those projects would bring new residential units to the area, along with some retail and community facility uses, a hotel, and a public school. There also several significant efforts to be undertaken within Flushing Meadows-Corona Park itself, as described below. No other development projects have been identified for completion between 2018 and 2032 in the study area.

With these projects, the east side of the Flushing River will continue to be transformed from an industrial area to an area characterized by higher-scale, mixed-use developments. The projects along the river will include waterfront esplanades, as required; together with initiatives proposed to improve connections between Downtown Flushing and the waterfront, it is anticipated that pedestrian activity and the visual environment along the Flushing River waterfront will continue to be enhanced. Other large-scale mixed-use developments are either under construction or planned for Downtown Flushing as well as Flushing north of Northern Boulevard. Collectively,

View east along 37th Avenue in Corona 33

View east from Flushing Bay Promenade access point 34

Views to Project Site from Study Area

View west to project site from Roosevelt Avenue at College Point Boulevard 35

Views to Project Site from Study Area

these projects are anticipated to increase the density of and bring new activity to these portions of the study area. In Corona, the bulk and use of projects to be completed by 2018 are anticipated to be consistent with the new zoning of this area. Some City capital funding has been allocated for streetscape improvements on Roosevelt Avenue west into Corona; however, there are no specific designs or timeline for implementation for this proposal. The reconstruction of the Roosevelt Avenue Bridge by NYCDOT is underway. It will involve the rehabilitation of the structure as well as improvements to the sidewalk.

Within Flushing Meadows-Corona Park, there would be incremental increases in height and bulk related to the proposed new stadiums and parking facilities at the USTA NTC site, but these would be modest relative to the existing facilities, and would not be inconsistent with the surrounding park context. With the exception of a modest change to park land acreage, the elimination of one lane of United Nations Avenue North, and the relocated connector roadway, the USTA NTC project would not result in any changes to natural features, open spaces, or streets in the study area.

The City, through DPR, is currently in discussions with a private entity for a lease covering the construction and operation of a new stadium for professional soccer purposes in an approximately 13-acre area within the northern portion of Flushing Meadows-Corona Park south of Roosevelt Avenue and eastward of the USTA NTC, just outside of the study area. As currently contemplated, a 25,000-seat stadium (with the ability to be expanded to 35,000 seats) would be constructed by 2016 on the present site of the Fountain of the Planets and land surrounding the fountain. In addition to the fountain, the stadium would displace four existing soccer fields, a basketball court, landscaped areas, and pathways, which would be relocated to other locations within the park.

Elsewhere in Flushing Meadows-Corona Park, ongoing capital improvement projects are being carried out by DPR to provide for up to date recreational facilities, including renovations and repairs to soccer fields and the creation of new volleyball courts. Although it is currently unfunded, DPR has identified repair of the tide gates within Flushing Meadows-Corona Park to improve drainage flow that affects existing park facilities as a priority project.

By replacing the Fountain of the Planets and surrounding pathways, the soccer stadium project would be anticipated to change the urban design of that portion of Flushing Meadows-Corona Park, and thus the pedestrian's experience of that portion of the study area. It is possible that the other capital improvement projects also could affect the urban design of the park, or views to visual resources.

G. PROBABLE IMPACTS OF THE PROPOSED PROJECT

URBAN DESIGN

2018 (PHASE 1A)

Project Site

In the future with the proposed project, by 2018 the Willets West portion of the project site would be developed with an entertainment and retail center of approximately 1.4 million gross square feet (see Figures 1-3a, 1-3b, and 1-5 of Chapter 1, "Project Description"). The new entertainment and retail structure would be oriented with its main entrance facing CitiField, creating a visual connection between the two buildings. The Willets West building would be

between approximately 40 and 105 feet tall, with the shortest portion of the building facing CitiField and the tallest portion at the center of the structure. It would have a footprint larger than the adjacent CitiField; however, while not yet fully designed, the treatment of the façade is anticipated to visually break up this bulk into smaller elements.

A six-level, approximately 63-foot-tall structured parking facility would be constructed on the western portion of the South Lot to accommodate a portion of the parking displaced from the Willets West area, replacing the existing surface parking on that portion of the lot. Within the District, an approximately 200-room (approximately 170-foot-tall) hotel and approximately 30,000 square feet of retail space would be constructed along the east side of 126th Street, along with a 20-foot-wide public esplanade.¹ A large surface parking area would be developed within the District east of the retail and hotel uses. A majority of this parking area would be converted to active recreational use a minimum of 6 months per year. Some of the potential recreational uses include street hockey, stickball, basketball and volleyball courts, a driving range, and batting cages.

The redevelopment of the District and the creation of the Willets West entertainment and retail complex in Phase 1A would considerably alter/transform the urban design of these portions of the project site, replacing a surface parking field and low-density auto-related, manufacturing, warehousing and distribution uses with new retail, hotel, entertainment, and recreational uses in new structures anticipated to be of contemporary design. The density of the project site would increase considerably, in particular on the Willets West site. As the Willets West and Roosevelt Avenue portions of the project site are not zoned, an FAR comparison of the future without and with the proposed project cannot be made; however, the Willets West development would be built to the FAR regulations of a C4-4 district, per the terms of the developer's contract with the City. For the District, the proposed development in Phase 1A would be less than what is allowed under the urban renewal plan. For Phase 1A, a special permit would be required to allow for the surface parking and open and enclosed privately operated recreational uses that are proposed for this phase of the project, as well as to address other sections of the Zoning Resolution. As described below, the development that would replace these uses in Phase 1B would comply with the District's zoning and special district regulations.

The proposed project—in particular the Willets West center, the proposed hotel, and the off-season recreational uses—would be anticipated to bring much more activity to the project site and enhance the pedestrian experience surrounding CitiField. The new uses at Willets West would complement existing retail and entertainment uses around the project site in the Flushing and Corona neighborhoods, as well as the CitiField and USTA NTC uses within Flushing Meadows-Corona Park.

Study Area

Phase 1A of the proposed project would not result in any changes to streets, buildings, natural features, or open spaces in the study area. If the traffic-related mitigation described in Chapter 21, "Mitigation" is implemented, however, the intersection of Northern Boulevard and 126th Street would be altered to include quick-curb and traffic signal louvers.

¹ The height of the hotel could be less than 170 feet in Phase 1A; however, this height is assumed for the purposes of a conservative analysis.

Willets Point Development

As described above, most of the no action projects that have been identified within the study area are anticipated to be complete by 2018. This would continue to change the visual appearance of the Flushing River waterfront, increase the density of the study area, particularly along the river; and bring notable changes to Flushing Meadows-Corona Park. Within this changing context, the scale of the retail, entertainment, hotel, and parking uses that would be developed in Willets West, the District, and the South Lot in Phase 1A would be consistent with those found within the study area, particularly within the dense commercial center of Downtown Flushing and developing waterfront area (as illustrated in View 35 of **Figure 8-20**). The proposed uses also would be more compatible with these adjacent neighborhoods than the existing industrial and auto-related uses. The entertainment and retail uses proposed for Willets West and the height and bulk of this structure would also be compatible with the adjacent CitiField stadium and other cultural facilities located within the boundaries of Flushing Meadows-Corona Park. The closest passive open spaces within the Flushing Meadows-Corona Park are located approximately ¼ mile south of Willets West, creating a substantial buffer between the two uses.

It is expected that the MTA property adjacent to the District would continue to be undeveloped in 2018, as well as 2028 and 2032, and would contain industrial uses that are the same as or similar to the construction and demolition debris recycling operation that exists there today. Although the recreational uses to be developed in the District would not be compatible with the industrial activities permitted on the nearby MTA property, the times during which the two uses would be proximate would be limited. Furthermore, the recreational uses would be consistent with the nearby portions of Flushing Meadows-Corona Park.

2028 (PHASE 1B)

Project Site

In Phase 1B, anticipated to be complete by 2028, the interim surface parking lot/recreational space created during Phase 1A within the District would be developed into a new neighborhood (see Figures 1-4 and 1-5 in Chapter 1, “Project Description”). The program for this development would be consistent with the District’s zoning and would include approximately 4.23 million square feet of development, including residential, retail, hotel, office, parking, and community facility uses, in addition to a public school and approximately six acres of open space.¹ This development is anticipated to be developed block by block, substantially as envisioned in the 2008 FGEIS. Specifically, six blocks and one superblock would be created, as well as their surrounding streets; the superblock would be divided by a landscaped pedestrian path along the current alignment of Willets Point Boulevard. In addition, two six-level (approximately 63-foot-tall) structured parking facilities would be constructed on the eastern portion of the South Lot and Lot D to replace the CitiField parking spaces located within the District in Phase 1A. Overall, the density of development on the project site would continue to increase. The Roosevelt Avenue portion of the project site is not zoned, and thus FAR comparison of the future without and with the proposed project cannot be made; however, the development on this portion of the project site would be built to the FAR regulations of a C4-4 district, per the terms of the developer’s contract with the City. For the District, the proposed development in Phase 1B

¹ It is possible that the hotel use developed in Phase 1B would be as an addition to the hotel developed in Phase 1A; in this scenario, the Phase 1B addition would bring the overall height of the structure to the 170 feet assumed in this analysis.

would be less than what is allowed under the urban renewal plan, but would be consistent with the approved zoning and special district's regulations.

Within the District, the previously-approved special district regulations would determine the placement of uses, building heights and setbacks, street hierarchies, maximum block dimensions, streetscape design, and basic site planning and design provisions within the District, as well as the general layout of the principal streets. Therefore, as contemplated in the 2008 FGEIS, the special district regulations would establish the basic form of the District, encouraging a pedestrian-friendly neighborhood environment, and ensuring that the new uses in the District are integrated into a cohesive site design. The uses proposed in Phase 1B would be consistent with and support the uses developed in the Willets West portion of the project site in Phase 1A, and would encourage pedestrian movement and activity between these two areas and surrounding CitiField.

Along 126th Street and adjacent streets, retail uses would line the ground-floor spaces and would generate new pedestrian activity at the site. The residential development would increase the use of the site and create a vibrant new community. The open spaces and landscaped sidewalks would create an attractive new development and, combined with the retail corridors, would create a pedestrian-friendly environment. Finally, the proposed development would complement CitiField by increasing retail and entertainment in the area.

The urban design of the redeveloped portion of the District in Phase 1B would differ substantially from that of the undeveloped portion of the District, where no changes would be made to the street grid, streetscape elements, grade, buildings, blocks, or uses. The buffer area between the developed and undeveloped portions of the District analyzed in the Staged Acquisition Alternative of the 2008 FGEIS and subsequent technical memoranda is not part of the proposed project; however, because streets in the undeveloped portion of the District would generally remain at their existing grade through Phase 1B, streets in the redeveloped portion of the District would be graded to slope down to the existing streets to the east, forming a physical barrier between the Phase 1B development and existing uses in the undeveloped portion of the District. There is anticipated to be some regrading in the street beds of the District to meet the grade of the new Van Wyck Expressway access ramps, which would be operational prior to the occupancy of the Phase 1B buildings. Any grade changes that would exist in Phase 1B would serve to provide a degree of visual and physical separation between the undeveloped and redeveloped portions of the District. Additionally, although there is no designated buffer area between the Phase 1B development and the adjacent undeveloped area, the new public open spaces to be provided east of Willets Point Boulevard and north of 35th Avenue also would serve to provide a visual buffer for the new residential and community facility uses from nearby auto-related uses.

Study Area

Phase 1B of the proposed project would not result in any changes to buildings, natural features, open spaces, or streets in the study area. Rather, the District as developed by 2028 would be more consistent with the urban design of neighboring Flushing than the existing buildings and uses in the District. Additionally, the bulk and type of uses proposed within the District in Phase 1B would be consistent with the ongoing development trends occurring along the Flushing River waterfront described above, including higher-density and mixed-use development.

The new open spaces to be developed in the District in Phase 1B would complement Flushing Meadows-Corona Park to the south and the Flushing Bay Promenade to the north, and would

Willels Point Development

provide an amenity for new residents and workers of the District and Willets West. The structured parking facilities proposed to be constructed on South Lot and Lot D also would be consistent with parking uses in Downtown Flushing and the portions of Corona in the study area, as well as at the adjacent Casey Stengel Bus Depot.

While the residential, school, commercial office, and community facility uses to be developed in the District in Phase 1B would not be compatible with the industrial activities permitted on the nearby MTA property, the District's regulations require the development of an eastern perimeter street, as well as a landscaped open space between 8 and 15 feet wide, which would provide a visual buffer between the redeveloped District and the adjacent MTA property. As described above, because streets in the undeveloped portion of the District would generally remain at their existing grade through Phase 1B, streets in the redeveloped portion of the District would be graded to slope down to the existing streets to the east, forming a physical barrier between the Phase 1B development and existing uses in the rest of the Willets Point peninsula, including the MTA property.

2032 (PHASE 2/RWCDS)

Project Site

In Phase 2, anticipated to be complete by 2032, the remainder of the District would be built out consistent with the area's previously-approved zoning and substantially as anticipated in the 2008 FGEIS (see Figure 1-6 in Chapter 1, "Project Description"). Upon completion of Phase 2, the District is anticipated to include: up to 5.85 million gross square feet of residential use; up to 1.25 million gsf of retail; approximately 500,000 gsf of office; up to 400,000 gsf of convention center use; up to 560,000 gsf of hotel use; up to 150,000 gsf of community facility use; approximately 230,000 gsf of public school use; and a minimum of 8 acres of publicly accessible open space. The number of proposed parking spaces within the District would be determined based on project-generated demand, but is anticipated to be no more than the 6,700 spaces identified in the 2008 FGEIS.

As described above, for the RWCDS, it also is anticipated that by 2032 Lot B could be developed with a one-story retail structure and a 10-story office building containing 184,500 sf of retail use and 280,000 sf of commercial use with associated parking.

The proposed project would implement the new street network through the District as analyzed in the 2008 FGEIS and consistent with the requirements of the URP and the Special Willets Point District. The proposed project would also result in the building uses, heights, arrangements, and block forms and open spaces anticipated in the 2008 FGEIS for the District.

As described in the 2008 FGEIS, due to the project site's proximity to LaGuardia airport, building heights within the District are set by height limits related to aerial runway approach "surfaces" which limit building heights to approximately 100 feet at the northern edge of the District, 150 feet on the southern edge of the District, and 218 feet on the west side of the District. The special district regulations also require that residential buildings above 120 feet follow additional guidelines in terms of bulk, orientation, and massing, and residential buildings are required to have interior courtyards with a minimum width of 60 feet. In order to maintain the pedestrian nature of the area, all off-street parking would be fully enclosed, either below grade or within the residential buildings, except along parts of Northern Boulevard and the eastern perimeter street where parking would be required to be screened within a structure.

Consistent with the special district's regulations, the proposed project also would develop a minimum of eight acres of publicly accessible open space by 2032. The open spaces would contain a combination of both active and passive uses. The central public open space would be on a triangular-shaped block along Willets Point Boulevard, near the center of the District. In addition to this central public open space, wide public access areas would surround the District and would be located along 126th Street, the south side of Northern Boulevard, the north side of Roosevelt Avenue, and the east side of the eastern perimeter street. These public access areas would include wide sidewalks, pedestrian amenity zones, or open areas with landscaping and plantings.

Overall, consistent with the conclusions of the 2008 FGEIS, the RWCDs would significantly alter the urban design of the project site, replacing predominantly low-density auto-related, manufacturing, warehousing and distribution uses with a new mixed-use neighborhood in the District. While the proposed project would significantly alter the urban design of the District, the proposed project would ultimately have a beneficial impact on the overall appearance and feel of the District. The new development that would result from the proposed project would enliven the area by creating new, usable streets. Along 126th Street and adjacent streets, retail uses would line the ground-floor spaces and would generate new pedestrian activity at the site. The residential development would increase the use of the site and create a vibrant new community. The open spaces and landscaped sidewalks would create an attractive new development and, combined with the retail corridors, would create a pedestrian-friendly environment. Finally, the proposed development would complement CitiField by increasing retail and entertainment spaces in the area. The build-out of the District also would be consistent with and support the development in the Willets West and Roosevelt Avenue portions of the project site, created in Phase 1A and Phase 1B. The RWCDs would create pedestrian-oriented developments on either side of CitiField, creating a dynamic, new, mixed-use neighborhood with pedestrian-scaled streetscapes and new entertainment and retail attractions and amenities to integrate this area with uses in neighboring Flushing and Corona.

Development on Lot B would convert a surface parking lot into a new, actively used location and would increase pedestrian activity to the area. In addition, the retail space would further the transformation of 126th Street into a pedestrian-friendly, retail-oriented destination. The office space would be in keeping with the office space that would be located in the District.

Study Area

The proposed project would introduce new building uses, bulk, arrangements, and types to the project site, which would complement existing development and projects currently under construction in the surrounding area. The proposed project would enhance the vitality of streets in the study area by introducing a variety of new uses that would increase pedestrian activity to the project site. The proposed project would also improve the appearance of the study area's streetscape by adding street lighting, signage, and general landscaping.

The proposed project would not result in any changes to buildings, natural features, open spaces, or streets in the study area. As noted in the 2008 FGEIS, the project would extend some study area streets into the District, including 34th Avenue and the access roadways along the northern and southern edges of CitiField. These new streets would be similar in width to those that exist in the study area and would travel on a similar trajectory as the existing streets. The newly created streets would link the District to the surrounding area and create new connector streets in the study area. The anticipated new connections to the Van Wyck Expressway would be designed in a manner similar to the existing connectors in the study area.

Overall, the RWCDs as developed by 2032 would have a positive effect on the urban design of the study area.

VISUAL RESOURCES

2018 (PHASE 1A)

Project Site

As described above, there are no visual resources on the project site, and thus no on-site resources would be affected by the proposed project in 2018. The development of the Willets West structure would limit views through that portion of the project site north to Flushing Bay; however, as noted above, these views are already constrained by the elevated Grand Central Parkway connector.

Study Area

Figures 8-21 through 8-25 provide an illustrative comparison of existing/2018 No Action conditions to 2018 With Action conditions from viewpoints within the study area. As illustrated in these figures, the development of the Willets West structure and the structured parking facility on the South Lot would alter views north from the Passerelle Ramp toward CitiField. From this location, the parking facility and the Willets West structure would be visible, but not prominent, beyond the utilitarian structures on the MTA Corona Rail Yard. The proposed hotel within the District would also be visible from this viewpoint, but would be consistent with the heights anticipated for this area in the 2008 FGEIS. CitiField and Arthur Ashe Stadium would remain notable elements in views from the ramp, and southward views to the Unisphere and the New York State Pavilion would not be altered. In views from North Corona, CitiField would be less prominent behind the Willets West development; however, the stadium, at approximately 265 feet tall, would be taller than the proposed retail and entertainment center and thus would still be visible. From the Flushing Bay Promenade, the new development would be visible, but as noted above, the elevated Grand Central Parkway connector already limits views from this location. Views to the Bay itself from the Promenade would not be disturbed. The proposed project would not alter or obstruct any views to visual resources in Downtown Flushing, or to the Flushing Meadows-Corona Park Pool and Rink. The proposed project also would improve the view corridor of 126th street by replacing the existing buildings with new development and beginning to create a pedestrian corridor, make the east side of the street more consistent with the west. Views along the other major street near the project site, Roosevelt Avenue, would not change substantially because of the view-constraining effects of the train viaduct overhead.

2028 (PHASE 1B)

Project Site

As described above, there are no visual resources on the project site, and thus no on-site resources would be affected by the proposed project in 2028.

Study Area

Figures 8-26 through 8-28 provide an illustrative comparison of existing/2028 No Action conditions to 2028 With Action conditions from viewpoints within the study area. As illustrated in these figures, the development of additional structured parking facilities on the South Lot and Lot D, and the build-out of the Phase 1A parking/recreational areas within the District, would

alter views north from the Passerelle Ramp. From this location, the various project site buildings would be visible beyond the utilitarian structures on the MTA Corona Rail Yard and adjacent to CitiField. The proposed hotel within the District would also be visible from this viewpoint, but would be consistent with the heights anticipated for this area in the 2008 FGEIS. CitiField and Arthur Ashe Stadium would remain notable elements in views from the ramp, and southward views to the Unisphere and the New York State Pavilion would not be altered. In views from North Corona, CitiField would be less prominent behind the Willets West development and with the backdrop of new development within the District; however, the stadium, at approximately 265 feet tall, would be taller than the proposed retail and entertainment center and thus would still be visible. From the Flushing Bay Promenade, the new development would be visible, but as noted above, the elevated Grand Central Parkway connector already limits views from this location. Views to the Bay itself from the Promenade would not be disturbed. The proposed project would not alter or obstruct any views to visual resources in Downtown Flushing, or to the Flushing Meadows-Corona Park Pool and Rink. The proposed project also would improve the view corridor of 126th street by replacing the existing buildings with new development and beginning to create a pedestrian corridor, make the east side of the street more consistent with the west. Views along the other major street near the project site, Roosevelt Avenue, would not change substantially because of the view-constraining effects of the train viaduct overhead.

2032 (PHASE 2/RWCDS)

Project Site

As described above, there are no visual resources on the project site, and thus no on-site resources would be affected by the RWCDS in 2032.

Study Area

Figures 8-29 through 8-32 provide an illustrative comparison of existing/2032 No Action conditions to 2032 With Action conditions from viewpoints within the study area.

The buildings resulting from the proposed project as well as the potential future development on Lot B would be visible from sections of Flushing Meadows-Corona Park; however, the MTA Corona Yards and Casey Stengel Bus Depot would block most views. The new structures on the project site would not detract from the visual appreciation of the park or the landscaping, trees, and open lawns that make the park a visual resource. As illustrated in **Figure 8-22**, the new buildings also would be visible in views from the Passerelle Ramp; however, as described above, the primary views from the ramp are south toward Flushing Meadows-Corona Park, and would not be obstructed by the structures that would result from the proposed project.

The proposed project and the potential future development on Lot B would not affect views to or from Flushing Bay, the Flushing Bay Promenade, or views to the 1964–65 World’s Fair structures in Flushing Meadows-Corona Park. The new development on the project site would be visible in views south from the Promenade, however this is not the primary view from this location, and the buildings would be partially obscured by the elevated transportation structures and by the new CitiField. The proposed project would not alter or obstruct any views to visual resources in Downtown Flushing, or to the Flushing Meadows-Corona Park Pool and Rink. The proposed project also would improve the view corridor of 126th street by replacing the existing buildings with new development and creating a pedestrian corridor, making the east side of the street more consistent with the west. Views along the other major street near the project site,

Roosevelt Avenue, would not change substantially because of the view-constraining effects of the train viaduct overhead.

In summary, this analysis finds that the proposed project would not result in any significant adverse impacts related to historic and cultural resources that were not addressed in the 2008 FGEIS. *

A. INTRODUCTION

This chapter assesses whether the reasonable worst-case development scenario (RWCDS) for the proposed project would result in any significant adverse impacts on natural resources that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

This analysis finds that the RWCDS would not result in significant adverse impacts on floodplains, wetlands, sediments, groundwater, terrestrial resources, aquatic resources, endangered, threatened species, or species of special concern and rare ecological communities, and Essential Fish Habitat (EFH) that were not addressed in the 2008 FGEIS and subsequent memoranda.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS and subsequent technical memoranda analyzed the potential for impacts on natural resources resulting from the Willets Point Development Plan. The 2008 FGEIS and subsequent technical memoranda concluded that the proposed Plan would not result in significant adverse impacts on natural resources within the study area.

C. METHODOLOGY

The natural resources assessment has been prepared in accordance with the 2012 *City Environmental Quality Review (CEQR) Technical Manual*. The project site comprises five areas: the Special Willets Point District (the “District”), Willets West, the South Lot, and Lots B and D. Because the Willets West, South Lot, and Lots B and D are all paved surface parking lots, and the District is also developed, the study area for the assessment of potential impacts to floodplains, wetlands, groundwater, and terrestrial natural resources comprises the project site and the areas immediately adjacent to it. An exception was made for the identification of threatened or endangered species, which were evaluated for a distance of at least 0.5 miles from the project site.

The study area for water quality and aquatic resources includes the aquatic resources within Flushing Bay and Flushing Creek.

Existing conditions within the study area were summarized from the following:

- Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps (FIRMs) and Best Available Flood Hazard Data (BAFHD);
- New York State Department of Environmental Conservation (NYSDEC) Tidal Wetlands Maps and Nature Explorer data;

Willets Point Development

- New York City Department of Environmental Protection (DEP) 2010 New York Harbor Water Quality Report;
- Draft Ecological Communities of New York State (Edinger et al. 2002);
- United States Fish & Wildlife Service (USFWS) National Wetlands Inventory (NWI) maps and Information, Planning and Conservation (IPaC) system list of Endangered, Threatened, Candidate, and Proposed species for Queens County, NY; and
- National Oceanic Atmospheric Administration (NOAA) National Marine Fisheries Service (NMFS) EFH maps and data.

Due to the developed condition of the project site and study area, there would be minimal difference in the potential for effects to natural resources for the three project phases (i.e., 2018, 2028, and 2032). Therefore, the evaluation of potential impacts from the construction and operation of these phases considers the potential impacts from the RWCDS for the year 2032, the full build out of the proposed project.

THE FUTURE WITHOUT THE PROPOSED PROJECT

In the future condition without the proposed project (the “No Action” condition), the District would continue to have the existing industrial and auto-related uses, and Willets West, the South Lot, and Lots B and D would continue to serve the parking needs of CitiField. It is assumed that the project site, which comprises the study area for the floodplains, wetlands, groundwater and terrestrial resources assessment, is assumed to would remain in its current condition for the three analysis years (i.e., 2018, 2028, and 2032), with the exception that climate change is projected to result in sea-level rise and associated changes in floodplain elevations, and that in the long term the City would undertake citywide efforts to improve resiliency, which would likely include measures to protect the area of Queens that includes Willets Point.

The assessment of water quality and aquatic resources for the No Action condition considered ongoing and proposed projects in the vicinity of the project site, including:

- Water quality and sediment quality improvements expected to occur as a result of regional and local programs; and
- Habitat enhancement or restoration activities associated with the New York/New Jersey Harbor Estuary Program (HEP) or Hudson-Raritan Estuary Ecosystem Restoration Project (HRE).

POTENTIAL IMPACTS FROM THE PROPOSED PROJECT

In the future with the proposed project, potential impacts on the floodplain, wetlands, groundwater, aquatic, and terrestrial resources from the RWCDS for the proposed project were assessed by considering the following:

- The existing water quality and aquatic resources of Flushing Bay and Flushing River in the vicinity of the project site;
- The existing natural resources within the project site; and
- The permanent and direct effects to these resources due to construction and operation of the proposed project (e.g., land disturbance and tree removal, and discharge of stormwater), and temporary indirect effects such as noise disturbances to wildlife during project construction and operation.

D. EXISTING CONDITIONS

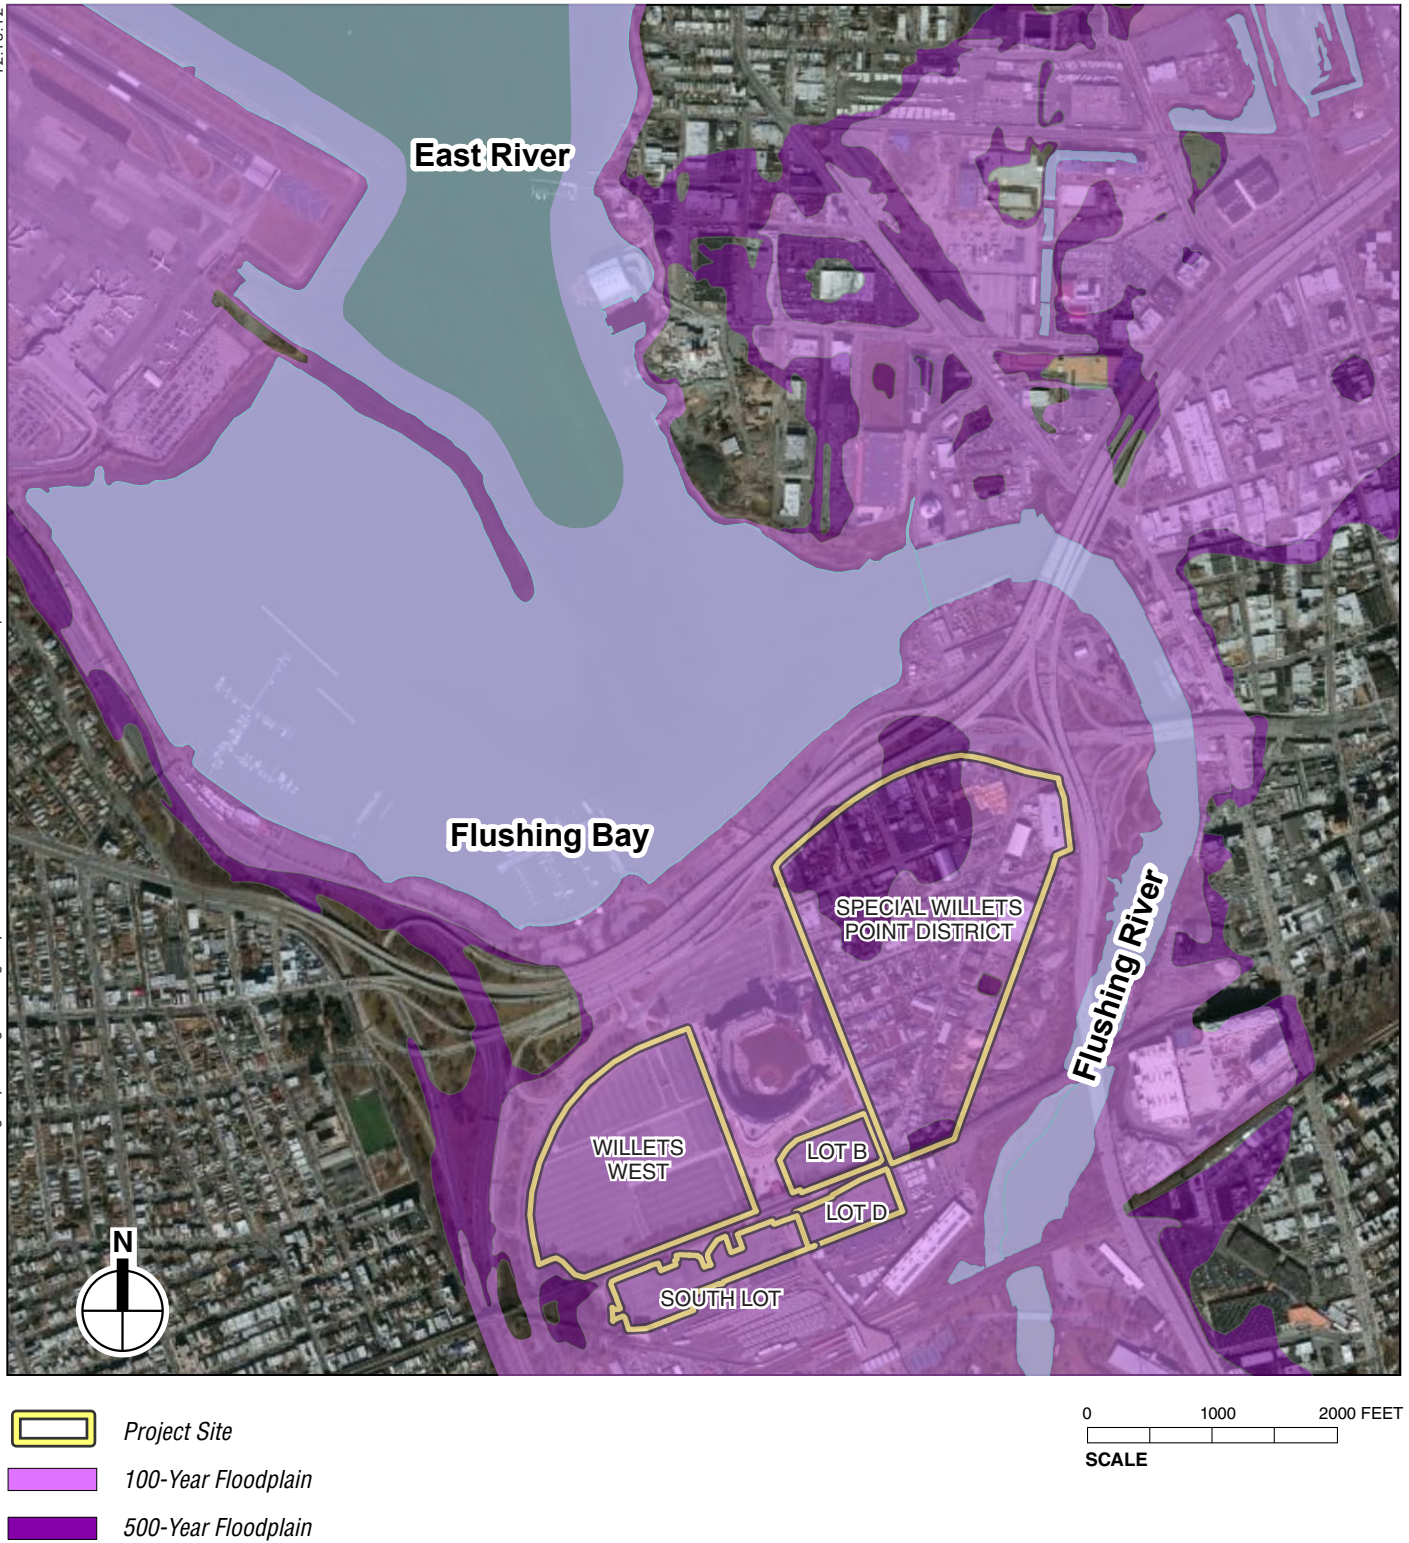

FLOODPLAINS

New York City is affected by local flooding (e.g., flooding of inland portions of the city from short-term, high-intensity rain events in areas with poor drainage), fluvial flooding (e.g., rivers and streams overflowing their banks), and coastal flooding (e.g., long and short wave surges that affect the shores of the Atlantic Ocean, bays such as Upper New York Bay, and tidally influenced rivers such as the Hudson River and East River, streams, and inlets [FEMA 2007]). Because the East River is tidal, its water level and that of Flushing Bay is controlled by the tidal conditions within the New York Bay, Long Island Sound, and the Atlantic Ocean. Within New York City, tidal flooding is the primary cause of flood damage. Coastal floodplains such as those present within the study area are influenced by astronomic tide and meteorological forces (e.g., northeasters and hurricanes), and not by fluvial flooding (FEMA 2007).

Figure 9-1 presents the 100-year floodplain boundary (Zone AE; the area with a 1 percent probability of flooding each year) and the 500-year floodplain boundary (Zone X; the area with a 0.2 percent probability of flooding each year) for the project site based on FEMA Flood Insurance Rate Maps (FIRMs) currently in effect. The 100-year flood elevation is at 14 feet National Geodetic Vertical Datum of 1929 (NGVD29), or approximately 13 feet when referenced to the North American Vertical Datum of 1988 (NAVD88). Willets West, the South Lot, and Lots B and D are within the 100-year floodplain. Most of the District is also within the 100 year floodplain, with the exception of three areas located in the northwest, along the eastern border and along Roosevelt Avenue that are within the 500-year floodplain. The portion of the District within the 500 year floodplain along Roosevelt Avenue was indicated as being within the 100-year floodplain in the 2008 FGEIS but is now within the 500-year floodplain on the basis of the updated FEMA FIRM for this portion of the project site.

Floodplain boundaries based on existing FIRMs are currently the only regulatory standard relating to elevations of new developments. On July 2, 2013, FEMA released the latest version of Best Available Flood Hazard Data (BAFHD)—a draft product preceding the publication of new FIRMs. FEMA encourages communities to use the BAFHD when making decisions about floodplain management and post-Hurricane Sandy recovery efforts, and these levels have been adopted by New York City for zoning purposes, allowing projects to account for higher base flood elevations for height and other zoning requirements. The 100-year floodplain elevations are the same as those in the currently effective FIRM in the northern portion of the District, north of 37th Avenue, and are one foot lower in all other areas of the proposed project.

On February 25, 2013, FEMA released Advisory Base Flood Elevation maps for areas in New York City, including the project site. The 100 year flood ABFE for Willets West and portions of the project site to the south of 37th Avenue is 12 feet NAVD88 or 13 feet NGVD 1929 (approximately 1 foot lower than the currently effective FIRM elevation). Within the District, for most of the area to the North of 37th Avenue, the 100 year ABFE is 13 feet NAVD88 or 14 feet NGVD29 (the same as the currently effective FIRM elevation), with the exception of an area mostly to the north of 34th Avenue, which is outside of the advisory 100 year floodplain. Although the ABFE is subject to further review, if it is adopted into the FIRM, the proposed project elements in Willets West and portions of the project site to the south of 37th Avenue where the ABFE differs from the existing FIRM elevation would comply with the updated flood elevation as required by the New York City Building Code.

Flood Hazard Areas
Figure 9-1

WETLANDS

The boundaries and classifications of the NWI- and NYSDEC-mapped wetlands that are known to occur in the vicinity of the District and Lot B and Lot D, are as described in the 2008 FGEIS. NYSDEC and NWI-mapped wetlands are not present on or adjacent to Willets West or the South Lot (see **Figures 9-2** and **9-3**). Willets West and the South Lot are paved surface parking lots and do not contain wetlands. The areas immediately adjacent to the project site are also developed and do not contain wetlands.

TERRESTRIAL RESOURCES

Since the publication of the 2008 FGEIS, development has occurred within the immediate vicinity of the District, Willets West, the South Lot, and Lots B and D, including the construction of CitiField, an associated parking lot, and the Department of Sanitation New York (DSNY) North Shore Marine Transfer Station. In addition, in December 2011, the City began construction on new sanitary and storm water mains to support the redevelopment of the District and adjacent areas. These projects did not include any new open space, and did not change the existing amount of vegetation, or natural habitat available to terrestrial wildlife within the immediate area of the project sites.

The ecological communities within the District and Lots B and D are unchanged from those described in the 2008 FGEIS, comprising industrial and auto-related uses and paved surface parking. These areas of the project site, as well as the paved surface parking of the South Lot and Willets West, including the new development described above, could be described as “Terrestrial Cultural” communities by Edinger et al. (2002). These are communities that are “either created and maintained by human activities, or are modified by human influence to such a degree that the physical conformation of the substrate, or the biological composition of the resident community is substantially different from the character of the substrate or community as it existed prior to human influence (Edinger et al. 2002).” For Willets West and the South Lot, dominant vegetation is limited to street trees that are located within parking lot medians of Willets West and around Willets West in the vicinity of Roosevelt Avenue and the northern part of the site along Shea Road.

WILDLIFE

The wildlife expected to occur within the District and Lots B and D would remain unchanged from the existing conditions presented in the 2008 FGEIS. These same urban-adapted species (e.g., Norway rat [*Rattus norvegicus*], rock pigeon [*Columba livia*], European starling [*Sturnus vulgaris*]) would be expected to occur in the vicinity of Willets West and the South Lot.

GEOLOGY AND SOILS

As described in the 2008 FGEIS, the Willets Point peninsula, where the District, Willets West, the South Lot, and Lot B and Lot D are located, is situated near the westernmost end of Long Island. Soils on the site consist primarily of fill material. The regional stratigraphy of Long Island, including the aquifers and confining layers, was formed from glacial tills and outwash sands of the Pleistocene Epoch. These layers lie unconformably over older deposits of the Cretaceous Period. The Cretaceous deposits lie over an impermeable bedrock surface dipping to the southeast. The bedrock consists of crystalline metamorphic rock of the lower Paleozoic Era.

0 1000 2000 FEET

 SCALE

GROUNDWATER

As described in the 2008 FGEIS, testing shows that contamination of the groundwater of the District and adjacent properties is typical to industrial areas and is likely limited to areas with shallow groundwater. As described in Chapter 10, “Hazardous Materials, conditions in the District, Lot B, and Lot D are not expected to have changed significantly from those summarized in the 2008 FGEIS. With respect to a new assessment of Willets West and the South Lot and a reassessment of Lots B and D, as described in Chapter 10, “Hazardous Materials,” evidence of a potential underground storage tank was observed on Lot D, though the Phase I ESA found no registered historical or current petroleum storage tanks. Similarly, the groundwater sampling of Lot B identified some substances (generally metals) at levels above the most stringent (drinking water) standards, but these were consistent with fill. The Willets West and the South Lot were found to be part of an “ash dump.” However, a Phase I ESA conducted on these sites found no evidence of historical or current petroleum storage tanks or other historical uses of concern.

AQUATIC RESOURCES

WATER QUALITY

As described in the 2008 FGEIS, the District is located along the western shore of Flushing Bay and the Flushing River. Willets West, the South Lot, and Lot B, and Lot D do not contain any surface waterbodies and do not border Flushing Bay or Flushing River.

The Flushing River and Flushing Bay are classified by NYSDEC as Use Classification I. Recommended uses for Class I waters are for secondary contact recreation and fishing, and water quality should be suitable for fish propagation and survival.

The DEP monitors water quality in New York Harbor, including Flushing Bay and the Flushing River, through its annual Harbor Survey. The results of recent surveys show that water quality in New York Harbor has improved significantly as a result of measures undertaken by the City. These measures include infrastructure improvements, the elimination of 99 percent of raw dry-weather sewage discharges, the reduction of illegal discharges, the increased capture of wet-weather-related floatables, and the reduction of toxic metals loadings from industrial sources by 95 percent (DEP 2002).

In the Upper East River–Western Long Island Sound survey region of the DEP Harbor Survey (which includes Flushing Bay and Flushing Creek) fecal coliform concentrations (an indicator of untreated sewage discharge) have demonstrated a downward trend over the last 20 years. Data collected in this region in 2009 and 2010, are consistent with this trend, with all but one station (located in Flushing Creek) meeting the Class I standards (DEP 2010). Average dissolved oxygen (DO)¹ concentrations also met the Use Classification I standards in 2009 and 2010 in both surface and bottom waters. Average chlorophyll-*a* concentrations² were not indicative of high nutrient concentrations in most

¹ DO in the water column is necessary for respiration by aquatic biota. The bacterial breakdown of high organic loads can deplete DO and result in low DO levels. Persistently low DO can degrade habitat and affect aquatic biota. Consequently, DO is one of the most universal indicators of overall water quality in aquatic systems.

² High levels of nutrients can lead to excessive plant growth (a sign of eutrophication) and depletion of DO. Concentrations of the plant pigment chlorophyll-*a* in water can be used to estimate productivity and the abundance of phytoplankton. Chlorophyll-*a* concentrations greater than 20 micrograms per liter (µg/L) are considered suggestive of eutrophic conditions (DEP 2010).

locations although confined areas such as the heads of Flushing Bay and Flushing River showed eutrophic conditions, particularly in mid-summer (DEP 2010). Secchi transparency¹ during 2010 was indicative of decreased water clarity, particularly in constricted waterways, likely due to high suspended solid concentrations of surface waters (DEP 2010).

AQUATIC BIOTA

The aquatic biota existing conditions remain unchanged from those described in the 2008 FGEIS. The composition of aquatic biota within Flushing Bay is expected to remain unchanged from the 2008 FGEIS conditions, even though water quality within the Upper East River-Western Long Island Sound continues to improve. As long as the substrate within Flushing Bay is dominated by fine grain material, many invertebrate species will continue to be excluded, limiting the diversity of the benthic macroinvertebrate community (even though the macroinvertebrate organisms can be abundant). Because of this lack of diversity in the benthic macroinvertebrate community, many fishes will make limited use of the habitat due to lack of preferred prey (NYCDEP 2011).

As discussed in the 2008 FGEIS, a 2003 field program found that the most abundant species were Atlantic silverside (*Menidia menidia*) and Atlantic sea herring (*Clupea harengus*), the latter as identified as a species with EFH in the study area. In addition, finfish sampling was conducted during August through October 2001 and July, September and October 2002 at the mouth of Flushing Bay and the inner Bay region. A total of 13 finfish species and 3 crab species were collected during the surveys. The primary fish collected were weakfish (41 percent), winter flounder (36 percent), Atlantic menhaden (9 percent) and striped bass (*Morone saxatilis*) (8 percent) (DEP 2012). The most abundant finfish eggs collected in the 2003 field program were cunner (*Tautoglabrus adspersus*) and Atlantic menhaden (*Brevoortia tyrannus*). The most abundant finfish larvae collected in the 2003 field program were herring (*Clupea* spp.), Atlantic menhaden, anchovy (*Anchoa* spp.), winter flounder, and goby (*Gobiosoma* spp.) (DSNY 2005). The most abundant macroinvertebrate species collected in 2003 were sevenspine bay shrimp (*Crangon septemspinosa*) and grass shrimp (*Palaemonetes vulgaris*). During the 2001 and 2002 field programs, three species of crabs were also collected including blue crab (*Callinectes sapidus*), Atlantic rock crab (*Cancer irroratus*) and green crab (*Carcinus maenas*) (DEP 2012). With respect to benthic habitats, data collected (1995 and 2012) in the bay show high abundances of pollution-tolerant species (e.g., *Oligochaeta*, *Leitoscoloplos robustus*) suggesting that the habitat quality is poor in this bay (Iocco et al. 2000; DEP 2012).

SEDIMENT QUALITY

The sediment existing conditions remain unchanged from those described in the 2008 FGEIS. Even with continued improvements in water quality, the substrates of Flushing Bay consist of fine silts and, as a result, the benthic community remains limited to pollution tolerant species (NYCDEP 2011). As discussed in the 2008 FGEIS, New York Harbor Estuary sediments,

¹ Secchi transparency is a measure of the clarity of surface waters. Transparency greater than 5 feet (1.5 meters) indicates relatively clear water. Decreased clarity can be caused by high suspended solid concentrations or blooms of plankton. Secchi transparencies less than 3 feet (0.9 meters) may be considered indicative of poor water quality conditions. Average Secchi readings in the Inner Harbor area have remained relatively consistent since measurement of this parameter began in 1986, ranging between approximately 3.3 and 6.1 feet (1.0 to 1.9 meters) (DEP 2010).

including the upper East River/Flushing Bay, are contaminated due to a history of industrial uses in the area. Backwaters such as Flushing Bay tend to be sediment traps; fine silts tend to accumulate in areas where tidal current velocities are reduced. The benthic habitat of Flushing Bay has been classified as soft silt or as silt with infauna. Some areas are presence of “stressed silt,” or silt with methane gas voids. Deeper collections near the confluence with the East River were characterized as azoic (silty bottoms without epifauna, infauna, or bacterial mats). The sediments in Flushing Bay are indicative of recently accumulated material that has limited potential to support a diverse benthic faunal community (Iocco et al. 2000; NYCDEP 2011).

THREATENED, ENDANGERED, RARE, AND SPECIAL CONCERN SPECIES AND SIGNIFICANT ECOLOGICAL COMMUNITIES

Requests for federally and state-listed species and ecological communities information were made to the USFWS, New York Natural Heritage Program (NYNHP), New York Department of State (NYSDOS), and National Marine Fisheries Service (NMFS) in preparation of the 2008 FGEIS. Responses from these agencies indicate that federally or state-listed species are not known to occur within the study area. Furthermore, the 2008 FGEIS concluded that habitat is not present for federally and state-listed species.

The USFWS’s IPaC system (accessed July 17, 2013) ~~“Queens County Federally Listed Endangered and Threatened Species and Candidate Species” list~~ (accessed November 5, 2012) ~~indicate lists~~ three federally listed species as occurring in Queens County: the piping plover (*Charadrius melodus*), roseate tern (*Sterna dougallii dougallii*), and seabeach amaranth (*Amaranthus pumilus*) (USFWS 2013²).¹ The study area comprises developed land that does not provide habitat for these species and they are not expected to occur within the project site. NYSDEC’s Nature Explorer database (accessed November 5, 2012) does not indicate any known occurrences of state-listed plant species or wildlife within an approximate 0.5-mile radius of the study area (NYSDEC 2012). Therefore, state-listed species are not expected to occur within the study area.

ESSENTIAL FISH HABITAT (EFH)

Table 9-1 lists the species and designated life stages identified as having EFH within the study area. This list is unchanged from the 2008 FGEIS with the exception of the addition of the dusky shark larval stage. Two EFH-designated species were identified during the 2003 sampling: the Atlantic sea herring was found to be abundant during the 2003 sampling event, as described above. In addition, the winter flounder (*Pleuronectes americanus*) was also collected during the 2003 survey.

¹ These species were not identified in the 2008 FGEIS.

Table 9-1

Essential Fish Habitat Designated Species for the Upper East River

Species	Eggs	Larvae	Juveniles	Adults
Pollock (<i>Pollachius virens</i>)			X	X
Red hake (<i>Urophycis chuss</i>)		X	X	X
Winter flounder (<i>Pseudopleuronectes americanus</i>)	X	X	X	X
Windowpane flounder (<i>Scophthalmus aquosus</i>)	X	X	X	X
Atlantic sea herring (<i>Clupea harengus</i>)		X	X	X
Bluefish (<i>Pomatomus saltatrix</i>)			X	X
Atlantic butterfish (<i>Peprilus triacanthus</i>)		X	X	X
Atlantic mackerel (<i>Scomber scombrus</i>)			X	X
Summer flounder (<i>Paralichthys dentatus</i>)		X	X	X
Scup (<i>Stenotomus chrysops</i>)	X	X	X	X
Black sea bass (<i>Centropristis striata</i>)			X	X
King mackerel (<i>Scomberomorus cavalla</i>)	X	X	X	X
Spanish mackerel (<i>Scomberomorus maculatus</i>)	X	X	X	X
Cobia (<i>Rachycentron canadum</i>)	X	X	X	X
Sand tiger shark (<i>Carcharias taurus</i>)		X ⁽¹⁾		
Dusky shark (<i>Carcharhinus obscurus</i>)		X ⁽¹⁾		
Sandbar shark (<i>Carcharhinus plumbeus</i>)		X ⁽¹⁾		X
Notes: ⁽¹⁾ This species does not have a free-swimming larval stage; rather it is a live bearer that gives birth to fully formed juveniles. For the purposes of this table, "larvae" for the sand tiger shark refers to neonates and early juveniles.

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

FLOODPLAINS

Floodplain elevations in the project site will change as a result of climate change and associated rises in sea level. As discussed in Chapter 16, "Greenhouse Gas Emissions and Climate Change," the New York City Panel on Climate Change (NPCC) projects that the 100-year floodplain elevation will increase 11 to 24 inches by the middle of the century (2050s middle range, 25th to 75th percentile), with a possible increase as high as 31 inches (high estimate, 90th percentile)¹. The NPCC predicts that intense hurricanes are "more likely than not" to increase in intensity and/or frequency, while possible changes in other large storms (e.g., Nor'easters) are uncertain. Regardless of storm frequency, the frequency of flooding events would increase because the sea level rise would result in flooding due to lesser storms, such that the current flood with a 1 percent chance of occurring in any given year would have a 5 percent chance of occurring in any given year by mid-century, and higher by the end of the century.

TERRESTRIAL RESOURCES

In the future without the proposed project, there would be no change to the terrestrial ~~resources~~ habitats, vegetation, or wildlife (i.e., ~~habitats and wildlife~~) of the District, Willets West, the South Lot, Lot B, and Lot D or adjacent properties (e.g., CitiField). These sites would remain as terrestrial cultural ecological communities with limited wildlife habitat.

¹ New York City Panel on Climate Change, *Climate Risk Information 2013*, June 2013.

AQUATIC RESOURCES

As described in the 2008 FGEIS, there are several proposed and ongoing projects aimed at improving water quality and aquatic resources in New York that have the potential to result in water quality and aquatic habitat improvements in the Flushing Bay and Flushing River. These projects are independent of the proposed project. The project descriptions provided below include updates since the 2008 FGEIS.

NEW YORK/NEW JERSEY HARBOR ESTUARY PROGRAM (HEP)

The New York/New Jersey Harbor Estuary Program (HEP) improvement projects as described in the 2008 FGEIS would occur without the proposed project and would continue through the proposed construction in 2018 to full operation of the project in 2032.

NEW YORK CITY DEPARTMENT OF ENVIRONMENTAL PROTECTION

As described in the 2008 FGEIS, DEP has taken several steps in recent years to mitigate discharges from combined sewer overflows (CSOs). In combination with improvements that have been made to Wastewater Pollution Control Plants (WPCPs), and the on-going Comprehensive City-Wide Floatables Abatement Plan,¹ the CSO improvements are expected to result in future improvements in coliform, dissolved oxygen, and floatables levels in the New York Harbor area. The improvements are expected to continue through the proposed construction in 2018 to the full operation of the project in 2032.

As required by EPA's CSO Control Policy, DEP initiated the development of the Long Term Control Plan (LTCP) Project in 2004. The LTCP Project is integrating CSO Facility Planning Projects and the Comprehensive City-Wide Floatables Abatement Plan, incorporating ongoing Use and Standards Attainment Program (USA) Project work, and developing Waterbody/Watershed Facility Plan Reports and the LTCP for each waterbody area, including Flushing Bay. As of 2011, DEP continues its development of the LTCP. The LTCP incorporates several cost-effective engineering solutions to address water quality issues of Flushing Bay, including increases in DO concentrations, decreases in coliform concentrations, and reductions in nuisance odors and floatables that are a consequence of CSO discharges. The Flushing Bay Waterbody/Watershed Facility Plan includes measures to maximize the wet weather capacity of Bower Bay WPCP, incorporates passive floatables controls, and plans for dredging five feet below mean lower low water (MLLW) to remove existing sediments of Flushing Bay to reduce odors. Following dredging it is anticipated that the bottom two feet would be capped to cover any exposed sediments, although the final design would be developed during the design and permitting phases.

NYCDEP has developed a "Green Infrastructure Plan" that provides a framework for CSO reduction strategies and investments over the next 20 years. The primary goal of the green infrastructure component is to manage runoff from 10 percent of the impervious surfaces in combined sewer watersheds through various detention and infiltration source controls such as rain barrels, swales, and green roofs. This plan includes green infrastructure for the drainage areas of Flushing River and Flushing Bay.

¹ New York City Department of Environmental Protection. 1999. Comprehensive Planning for Control of CSO Floatables and Settleable Solids in New York City. Available: <http://www.hydroqual.com/Papers/wmcmillin/02/Small/index.htm>.

UNITED STATES ARMY CORPS OF ENGINEERS

In addition to the dredging proposed by DEP, the United States Army Corps of Engineers (USACE) is developing engineering and design plans for the maintenance dredging of the Flushing Bay and Flushing River navigational channel.

OTHER PROJECTS

As part of ongoing infrastructure work to better manage stormwater within the Willets Point District, the New York City Economic Development Corporation (EDC) received authorization from the USACE in December 2010 and from NYSDEC in February 2011. The new 126th Street outfall combined with re-use of the existing 127th Street outfall would contribute to improved water quality conditions within Flushing Bay and would be operational by 2018.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

Due to the developed condition of the project site and study area, there would be minimal difference in the potential for effects to natural resources for the three project phases (i.e., 2018, 2028 and 2032). Therefore, the evaluation of potential impacts from the construction and operation of these phases considers the potential impacts from the RWCDS for the year 2032, the full build out of the proposed project.

FLOODPLAINS

On the basis of the currently effective FEMA FIRM, Willets West, the South Lot, and Lots B and D are within the 100-year floodplain. Most of the District is also within the 100-year floodplain, with the exception of three areas located in the northwest, along the eastern border and along Roosevelt Avenue that are within the 500-year floodplain. Thus, in some locations, particularly within the District, new fill would be required to grade and raise the project site structures above the 100-year flood elevation, consistent with the New York City Building Code¹ and any future revisions to these requirements that may be made on the basis of FEMA ABFEs, BAFHD and eventually updated FIRMs. According to the BAFHD, the 100-year floodplain elevations are the same as the current FIRM in the northern portion of the District, north of 37th Avenue, and are one foot lower in all other areas of the proposed project. Factoring in recently updated (June 2013) New York City Panel on Climate Change projections of sea-level rise, it is expected that the 100-year floodplain elevation will increase 11 to 24 inches by the middle of the century (2050s middle range, 25th to 75th percentile), with a possible increase up to 31 inches (high estimate, 90th percentile) (see Chapter 16, “Greenhouse Gas Emissions and Climate Change”).

Under the current plan, the District portion of the project site and Willets West would be graded and elevated one foot above the current FIRM floodplain (which is two feet above the BAFHD for all project areas except a portion of the District north of 37th Avenue) such that the occupiable floors would be at an elevation of 14 feet (NAVD88) and would meet the requirements of the New York City Building Code. Therefore, the proposed design would

¹ As specified in Appendix G: “Flood Resistant Construction” of the *New York City Building Code* ¹ for the applicable building category (see Table 1604.5 of the *New York City Building Code* or Table 1-1 of Appendix G to the *New York City Building Code*), and revisions to these requirements prior to construction.

reduce the vulnerability to flood damage as compared with existing conditions, as well as offer resilience to the 1 to 2 feet of sea-level rise expected to occur by mid-century (2050s). To account for climate change, the occupiable floors of the proposed buildings are designed to be at an elevation of 1 to 2 feet above the ABFE to provide resilience to the 1 to 2 foot rise in future sea level that is projected by the New York City Panel on Climate Change. Changes to the grade elevation are expected would likely to occur in phases. During Phase 1A, the majority of the project site would remain at the existing grade and only the hotel and commercial spaces would be built at a higher grade above the floodplain elevation. No internal, private streets would be built during Phase 1A. The remainder of the extent of Phase 1A and 1B would be raised above the 100-year flood elevation prior to completion of the development of Phase 1B in 2028. Those grade changes would either occur through new fill and retaining walls or by building atop basements that raise the finished floor height above the floodplain elevation. Grade transitions would be created between the new streets in Phase 1B and the existing street grades that would remain in the Phase 2 area until that area is raised prior to completion of Phase 2 development in 2032.

As discussed in further detail in Chapter 16, “Greenhouse Gas Emissions and Climate Change,” further measures will be investigated and implemented within the proposed project site to the extent practicable. Prior to commencement of construction for each phase of the project, the project sponsor will work with the Mayor’s Office of Environmental Coordination (MOEC) to develop a plan for resilience of the proposed area to be developed in that phase from future flood levels, considering the types of uses proposed; the plan will be designed with the goal of making the project area resilient to end-of-century flood levels in residential areas, and mid-century in other areas. This may be achieved via a combination of practicable measures within the project, potentially including grade change, protection of critical infrastructure, and design elevations, and storm surge protection measures if those are practicable and relevant within the area to be developed in that phase, along with areawide or waterfront measures to be undertaken by the City outside of the project area, as appropriate. While the plan for each phase may not identify all details necessary for the long-term implementation, it will identify the practicable measures needed for that phase of the project and conceptual measures being considered or undertaken by the City beyond the project site. The plan will be consistent with the City’s citywide coastal protection policy as described in *A Stronger, More Resilient New York* through the 2050s.

For sea level rise beyond the 1 to 2 feet projected for mid-century, the most practicable solutions to increase resiliency may include areawide and/or waterfront solutions, which may need to be implemented off-site by the City. While the City has not yet undertaken the studies needed to select the most effective measure to offer flood protection to the area of Queens that includes Willets Point, some measures that may be undertaken by City agencies in the future include:

- Coastal edge elevation measures;
- The City’s tide gate repair study at Flushing Meadows, if relevant; and
- Integrated flood protection and storm surge barriers.

The City would also have the authority to require an increase in the proposed grade of the District at the time of such future development via changes to the New York City Building Code, by incorporating changes to the flood level provisions, or via other New York City Executive Orders, rules, or regulations, as may be issued at that time.

By striving to incorporate reasonable strategies that would increase resilience to the likely projected effects of climate change through the 2050s, the proposed project would go beyond the

Willets Point Development

legal requirements to address the potential effects of climate change on a project and would be consistent with the City's Special Initiative for Rebuilding and Resiliency policy. As part of citywide efforts to improve coastal resiliency, it is anticipated that solutions for protecting the area over a longer time horizon will be developed before sea levels rise beyond 1 to 2 feet.

Because the 100-year floodplain within and adjacent to the study area is affected by coastal flooding (rather than local or fluvial flooding) as a result of astronomic tides and meteorological forces, flooding conditions in the project site and surrounding area would not be affected by construction or regrading/filling that would occur for the proposed project.

~~Therefore, the design for the structures for the RWCDs would minimize the potential for public and private losses due to flood damage under current flood conditions, and no significant adverse impacts are expected. Because the 100 year floodplain within and adjacent to the study area is affected by coastal flooding (rather than local or fluvial flooding) as a result of astronomic tides and meteorological forces, flooding conditions in the project site and surrounding area would not be affected by construction or regrading/filling that would occur as part of the RWCDs.~~

WETLANDS

As described in the 2008 FGEIS, NYSDEC and NWI-mapped wetlands would not be impacted as a result of the proposed project within the District, and Lots B and D. Similarly, because there are no wetlands present within Willets West or the South Lot, the RWCDs would not adversely affect wetland resources.

TERRESTRIAL RESOURCES

ECOLOGICAL COMMUNITIES

The ecological communities of the study area are developed with buildings, streets, and parking lots. Vegetated areas are limited to successional urban-tolerant species of little ecological value. As described in the 2008 FGEIS, the proposed project would not have a significant adverse impact on ecological communities in the District and Lots B and D. Willets West and the South Lot are paved parking lots. Within Willets West, vegetation is limited to street trees located along the perimeter of the property and in the parking lot. Tree replacement and protection would comply with the New York City Department of Parks and Recreation's (NYCDPR) applicable rules and regulations. Trees under the jurisdiction of NYCDPR may not be removed without a permit pursuant to Title 18 of the Administrative Code of the City of New York. Chapter 5 of Title 56 of the Rules of the City of New York establishes rules for valuing trees that are approved for removal to determine the appropriate number of replacement trees. A method to calculate the number of replacement trees as per the New York City tree replacement code, such as the caliper replacement method, would most likely be used to quantify the size and number of trees that would be required to replace those removed from the project sites. Measures to protect existing trees would include protection plans to minimize impacts to the critical root zones, trunks, and canopies. The potential loss of trees and the existing "terrestrial cultural" ecological communities within the project site, which are common to the New York metropolitan area, would not result in significant adverse impacts to vegetation resources within the region.

WILDLIFE

Potential impacts to wildlife from construction activities for the project generally include noise and visual disturbances. Site preparation activities and construction of the RWCDS would generate noise and anthropogenic activity. However, impacts to wildlife would be minimal because wildlife within the study area consists of urban-adapted, highly disturbance-tolerant species. The species of wildlife in the area are ubiquitous throughout the city and commonly inhabit areas with extensive levels of human disturbance and degraded habitat conditions. Wildlife occurring in the area would not be expected to be significantly impacted by the noise and other anthropogenic disturbances generated by project construction.

The RWCDS for the proposed project would create conditions for wildlife that would be similar to those currently present within the project site, and would thus support wildlife species similar to those currently using the project site. Landscaped areas resulting from the RWCDS for the proposed project would have the potential to improve on the quality of the habitat available for urban tolerant wildlife species currently present within the study area, and would improve the suitability of the project site as migratory bird stopover habitat.

The increased human activity that would occur as a result of the RWCDS for the proposed project, when compared to the future without the proposed project in 2032 would not be expected to adversely affect disturbance-tolerant wildlife using the limited habitats within the study area. Operation of the RWCDS for the proposed project in 2032 would result in more buildings with windows in the area with which birds would have the potential to collide, and thus daytime bird collision risk would be slightly greater than under the existing conditions. Although birds are known to collide with tall artificial structures at night, the overwhelming majority of bird collisions with buildings occur during the daytime when lower story windows reflect images of nearby trees and other vegetation, and sky (Gelb and Delecretaz 2006, 2009; Klem et al. 2009).

The additional buildings and glass coverage that would occur in the area by 2032 would not be expected to increase the likelihood of nighttime bird strikes, which is considered to be extremely low due to the limited height of the proposed buildings. Nighttime collisions of birds with artificial structures are often strongly related to structure height (Kerlinger 2000). Most birds migrate at altitudes of 656 to 2,461 feet (Able 1970, Mabee et al. 2006) and rarely fly below 295 feet (Mabee and Cooper 2004). Heights of the proposed buildings would be low, ranging from 63 to 218 feet. As such, none of the proposed buildings would extend into air space commonly used by migrating birds, and nighttime collisions of birds would be rare.

Daytime collision potential would be highly dependent on the building designs and the surrounding landscaping. The landscaped habitat that would be available within the project site by 2032 would be used most likely by common, resident bird species, such as house sparrows and European starlings, which rarely collide with windows (O'Connell 2001). Therefore, consistent with the conclusions in the 2008 FGEIS, the construction and operation of the RWCDS would not result in direct or indirect significant adverse impacts on wildlife.

GEOLOGY AND SOILS

As discussed in Chapter 10, "Hazardous Materials," management of wastes generated in the cleanup and redevelopment of the project site will be conducted in accordance with applicable federal, state, and local regulatory requirements and with oversight of NYC regulatory agencies. As a result, the proposed project would have the potential to have a direct benefit to soils of the

study area. Therefore, consistent with the conclusions in the 2008 FGEIS the RWCDs would not result in direct or indirect adverse impacts to soils of the study area.

GROUNDWATER

As discussed in Chapter 10, “Hazardous Materials,” a construction health and safety plan (CHASP) and Site Management Plan (SMP) for site remediation, excavation, and redevelopment would be developed and would include detailed procedures for managing known contamination issues (e.g., tank removal, and soil and groundwater remediation of existing petroleum spills, excavation, and removal of existing septic tanks or fields, floor drains, and historic fill), as well as any unexpectedly encountered contamination issues. As a result, the proposed project would have the potential to result in a net benefit to groundwater of the study area. In addition, as discussed in Chapter 10, “Hazardous Materials,” pile driving for new construction would not be anticipated to significantly change the overall groundwater flow regime. Thus, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts related to groundwater quality.

AQUATIC RESOURCES

WATER QUALITY AND AQUATIC BIOTA

No in-water construction activities would result from the construction of the RWCDs. Soil disturbing activities associated with construction all phases of the RWCDs would be conducted in accordance with the NYSDEC State Pollutant Discharge Elimination System (SPDES) General Permit for Stormwater Discharges from Construction Activity (GP-0-10-001). Erosion and sediment control measures to be implemented during construction activities would be specified in the stormwater pollution prevention plan (SWPPP). With the implementation of these measures, stormwater discharged through the existing stormwater outfalls would not result in significant adverse impacts to water quality and aquatic biota of Flushing Bay. Additionally, with implementation of the proposed site remediation (detailed in Chapter 10, “Hazardous Materials”) construction and operation of the RWCDs would reduce the potential for contaminants to enter Flushing Bay and the Flushing River, thereby having the potential to improve the water quality of these waterbodies.

As discussed in Chapter 11, “Water and Sewer Infrastructure”, all phases of the RWCDs would be consistent with the City’s goal to reduce CSO events by requiring construction and maintenance of a separate storm and sanitary sewer system. The new sanitary sewer infrastructure would connect to the Bowery Bay Wastewater Treatment Plant (WWTP) via the City’s sewer system and would not cause the plant to exceed its capacity or SPDES permit limit of 150 million gallons per day (mgd). As such, there would be no impacts to water quality of the East River. Water quality of the East River in the vicinity of the Bowery Bay WPCP would continue to meet the Use Class I water quality standards. The 2008 FGEIS found that there would be no significant increase in the frequency of CSO events as a result of the Willets Point Development Plan because CSOs primarily relate to stormwater inputs, which greatly exceed sanitary flow rates during storm events. As a result of this conclusion, it is anticipated that the sanitary flow from the RWCDs, (lower than projected in the 2008 FGEIS) would not significantly affect the number of annual CSO events. Moreover, water conservation measures and low-flow fixtures as required by New York City Plumbing Code (Local Law 33 of 2007) would be employed to minimize sanitary sewage flow to the existing combined sewer system.

Stormwater runoff from the project site during all phases of the RWCDS would be treated in accordance with the SWPPP, and conveyed to Flushing Bay through a separate storm sewer system in accordance with an ADP that would be developed by the Queens Development Group, LLC (QDG) and approved by DEP.

Given that the District currently lacks sewer infrastructure and stormwater from the existing industrial uses flows heavily into Flushing Bay, discharges from the proposed system in the future with the RWCDS in 2018, 2028, and 2032 would be a substantial improvement over current conditions. Further, the proposed project would be consistent with the goals of DEP's NYC Green Infrastructure Plan by managing stormwater at the site. Overall, implementation of the new system is expected to improve stormwater quality and, in turn, improve water quality in Flushing Bay by addressing existing chronic flooding, improving the quality of the soil substrate of the site, providing direct drainage to storm sewers, and incorporating sustainable design features, where feasible, to reduce discharge volume and increase the quality of stormwater discharges. Therefore, consistent with the conclusions of the 2008 FGEIS, the construction and operation of the RWCDS would not result in significant adverse impacts to water quality and aquatic biota of Flushing Bay and the Flushing River.

SEDIMENT QUALITY

No in-water construction would take place in Flushing Creek and Flushing Bay as a result of the RWCDS. Therefore, the sediments of Flushing Creek and Flushing Bay would not be impacted during the construction or operation of the proposed project. Furthermore, the dredging plans for Flushing Bay, as proposed by DEP and as part of USACE's navigational channel clearance maintenance, would not be impacted by the construction or operation of the proposed project.

THREATENED, ENDANGERED, RARE, AND SPECIAL CONCERN SPECIES AND SIGNIFICANT ECOLOGICAL COMMUNITIES

As discussed in the 2008 FGEIS and above under "Existing Conditions," federally and state-listed species and ecological communities are not known to occur within the study area nor is habitat present. Therefore, consistent with the conclusions of the 2008 FGEIS, the RWCDS would not result in adverse impacts to federally and state-listed species.

ESSENTIAL FISH HABITAT

As discussed above, no significant adverse impacts to aquatic biota are expected as a result of the proposed project. Construction would not occur within Flushing Bay or Flushing Creek. Therefore, consistent with the conclusions of the 2008 FGEIS, the RWCDS would not result in significant adverse impacts to EFH.

A. INTRODUCTION

This chapter assesses the potential for the presence of hazardous materials at the site of the proposed project. The analysis includes updates to the proposed project and background conditions since the 2008 FGEIS and assesses whether any changed background conditions or differences in elements between the proposed project and the development program analyzed in the 2008 FGEIS and subsequent technical memoranda would result in significant adverse impacts related to hazardous materials.

Consistent with the Staged Acquisition Alternative analyzed in the 2008 FGEIS as well as the Adjusted Plan and Updated Plan analyzed in subsequent technical memoranda, the proposed project would phase remediation and redevelopment of the Special Willets Point District. In the proposed project, Phase 1A (2018) would commence with the remediation to standards appropriate for multi-family residences of an approximately 23-acre portion of the District and development of this area with hotel, retail, and interim surface parking/recreational uses. These interim uses would be developed on an impermeable surface. Remediation of areas to be developed in Phase 1A would be completed prior to 2018. In Phase 1B (2028), the interim parking/recreational space created during Phase 1A within the District would be redeveloped with residential, retail, office, hotel, community facility, public school, and public open space uses. Remediation of the portion of the District not already developed in Phases 1A and 1B to standards appropriate for multi-family residences is assumed to be completed prior to 2028, and thus before the commencement of the Phase 2 development.

The analysis provided below considers the Willets West and South Lot portions of the project site, which were not assessed in the 2008 FGEIS, and reassesses the previously analyzed District, Lot B, and Lot D portions of the project site.

PRINCIPAL CONCLUSIONS

This analysis finds that, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts related to hazardous materials.

As described below, Phase I Environmental Site Assessments (ESA) have been performed for the entire project site. These identified the potential for contamination due to current and past usage:

- **Special Willets Point District:** sampling undertaken as part of previous Phase II ESAs confirmed that contamination is present and is expected to be widespread.
- **Lot D:** Tires and apparently empty 35-gallon drums were present on Lot D. Evidence of a potential underground storage tank was observed. However, the Phase I ESA found no registered historical or current petroleum storage tanks, which indicates that the tank may have been installed/operated prior to tank registration requirements or may have been of too small a capacity to require registration. Prior to development, a Phase II ESA would be

performed for Lot D to assess potential contamination and assist in preparation of any necessary remedial plans and health and safety procedures.

- **Lot B:** Subsurface sampling identified fill material (including cinders, wood, brick, metal, and asphalt) overlying marsh deposits. This was consistent with historical information regarding prior conditions and uses. The soil sampling did not identify significant contamination (the results were consistent with those usually found in historical fill materials in New York City). Similarly, the shallow groundwater sampling identified some levels (generally of metals) above the most stringent (drinking water) standards but these were consistent with the levels of metals found in the soil samples of the fill material. The soil gas sampling found elevated levels of methane (potentially attributable to the marsh deposits).
- **Willets West and South Lot:** The Phase I ESA indicated that these portions of the project site were also part of the much larger “ash dump” in the early part of the 20th century. Around 1950, Willets West was paved and used for parking until 1964, when Shea Stadium opened on the property. The South Lot has been used for parking since the mid 1960s. In 2009, Shea Stadium was demolished and has since been used for parking with multiple small ticketing structures. The Phase I ESA found no evidence of historical or current petroleum storage tanks or other historical uses of concern. Prior to development, a Phase II ESA would be performed for the Willets West and South Lot areas to assess potential contamination and assist in preparation of remedial plans, if necessary, and health and safety procedures to be implemented during construction.

By implementing investigation and remediation measures including appropriate engineering/institutional controls into the development, as well as incorporating health and safety procedures into the construction, it is expected that no potential exposure or significant adverse impacts related to hazardous materials would occur during or after construction of the proposed project. Construction of the proposed project would involve both demolition of all existing structures (some of which are believed to contain asbestos containing materials, lead-based paint, and polychlorinated biphenyls containing electrical components) and a variety of earthmoving/excavating activities that would encounter subsurface contamination (e.g., petroleum, solvents, polychlorinated biphenyls, or other contaminants associated with the area's historical filling), particularly within the District. To avoid the potential for significant adverse impacts related to hazardous materials the proposed project would include appropriate health and safety (e.g., dust control and air monitoring) and comprehensive investigative/remedial measures (e.g., delineating and excavating contaminated soils and disposing of them off site at an appropriately licensed facility) that would be undertaken in conjunction with the excavation and disturbance of fill material. Understanding that the entire area includes ash fill and that within the project site fill material would remain, residual soil and groundwater contamination would need to be accounted for in any new development. Engineering controls to address the residual contamination can include a variety of measures including but not limited to capping surfaces, groundwater controls to prevent migration, and systems beneath buildings to prevent infiltration of soil vapor.

While development of the District is contemplated to occur in phases, Phase 1A will incorporate a comprehensive site investigation and associated remedial action that will remove areas of significant contamination and prepare the site for development. When subsequent development takes place over or adjacent to these areas, measures will be undertaken to prevent human exposure. These will include stringent measures for dust control, procedures for dewatering, proper handling and disposal or backfill of excavated material and prevention of stormwater pollution from runoff. Additional measures (e.g., the mandatory implementation of appropriate

health and safety procedures) will be undertaken to prevent exposure following development during intrusive work and subsurface utility repairs at developed sites.

Institutional controls would be used to ensure that the various measures outlined above would be implemented, all lots in the project site would have restrictions placed on them. Specifically, for the District, these restrictions include the (E) designations already placed following the 2008 FGEIS and potentially State of New York Brownfield Cleanup Program (BCP) requirements, should any developments enter into this (voluntary) program. For lots outside of the District, the restrictions would be incorporated into the development agreements and/or amended leases for each lot. These lots are and would remain in City ownership.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS and subsequent technical memoranda identified the likelihood of hazardous materials presence at the project site from: placement of historical ash fill (approximately 10 to 12 feet thick), beginning in the mid- to late 1800s, and continuing through the early 20th century; and releases of petroleum products and chemicals from existing and historic commercial and industrial facilities (especially within the District).

In addition to contamination from releases to soil, contamination of groundwater was also identified. Groundwater was encountered at relatively shallow depths of between 4 to 9 feet below grade, generally within the fill material. Although groundwater flow varies and may be tidally influenced in some areas, the overall flow was expected to be toward Flushing Bay and Flushing River to the north and east of the District.

Existing structures at the project site were known or suspected to include asbestos containing materials (ACM), lead-based paint (LBP) and polychlorinated biphenyls (PCB) containing equipment.

SPECIAL WILLETS POINT DISTRICT

A February 2005 District-wide Phase I ESA (and additional individual Phase I ESAs completed subsequently on selected parcels when access was obtained) assessed the potential for hazardous materials based on: a reconnaissance from public rights-of-way (but generally no access to private property); a review of historical maps; federal and state regulatory records; and topographic and geologic/hydrogeologic data.

Overall, based on the general conditions noted during the public right-of-way evaluation, the majority of the sites operating in the District were believed to contain potential concerns over waste discharge and other issues related to individual site conditions. Historical uses included metal wholesaling, recycling, various automotive body and mechanical repair operations and scrap parts sale and distribution. During the reconnaissance, metal construction debris and other recyclable metal was observed in addition to all types of car parts (e.g., radiators, gas tanks and batteries). Contamination typical for this land use includes automotive wastes (e.g., waste oil, gasoline and radiator fluids), PCB-contaminated wastes and oils, solvents, heavy metals and lead acid batteries. Since there are no municipal sewer systems servicing the area, wastewater discharge to leach fields, septic tanks and underground tanks would represent a potential direct pathway for contaminants to reach the subsurface and shallow groundwater.

Willets Point Development

The regulatory databases searched as a part of the Phase I ESA identified numerous registered active petroleum storage tanks (and based upon the time period that the site has been occupied by these types of businesses, it is possible that other unregistered tanks are also present), as well as a limited number of open-status petroleum spills (though other spills may have occurred and not been reported to the State).

Based on the findings of the District-wide Phase I ESA, a subsurface investigation (Phase II ESA) was conducted. The Phase II investigation included collection and laboratory analysis of soil and groundwater samples, however, similar to the Phase I, sampling and access was limited to public-rights-of-way, along street and sidewalk areas for the area-wide Phase II. Permission was subsequently obtained for access to one private parcel to perform a limited Phase II ESA. The soil sampling within the streets and public rights of way identified detectable concentrations of VOCs in 20 of the 22 soil samples analyzed. Only two of these exceeded the then-used New York State Department of Environmental Conservation (NYSDEC)-Recommended Soil Cleanup Objectives (RSCOs), specifically for gasoline-related VOCs. Detectable levels of SVOCs were found in all samples, generally below or within one order of magnitude above the RSCOs. The compounds and levels detected were typical of urban fill material though contributions from petroleum or other on-site sources could not be ruled out. The metals analyses showed several metals at concentrations above the RSCOs including samples with arsenic, barium, nickel, copper, and zinc at more than one order of magnitude above the RSCOs. Lead concentrations ranged up to 3,310 parts per million (ppm), but only three samples exceeded 400 ppm (the level typically used in situations where children could be exposed to surface soils). Pesticides were detected in 12 of the samples but none exceeded RSCOs. Eight samples had detectable concentrations of PCBs but none exceeded NYSDEC RSCOs (1 ppm). Ethylene glycol (the most common antifreeze ingredient) was not detected.

Groundwater sampling within the streets and public rights of way showed levels above drinking water standards (results were compared to these standards even though groundwater is not used as a source of drinking water). Four of the seven samples had levels of VOCs typically associated with gasoline above these standards. SVOC levels exceeded the drinking water standards in two samples but the compounds detected could have been petroleum or fill-related.

Soil and groundwater contamination consistent with petroleum was identified at the private parcel. Given these results and the findings of the Phase I ESA, petroleum and other contamination is expected to be widespread on private properties within the District.

To avoid the potential for significant adverse effects, the 2008 FGEIS outlined a variety of presumptive remedial measures as well as accompanying engineering controls that would be implemented prior to and during construction. These included:

- Procedures for pre-demolition removal of asbestos and appropriate management of LBP and PCB-containing equipment.
- Additional subsurface investigation, both of development sites and areas within the current roadways, to further assess and remediate conditions.
- Development of a construction health and safety plan (CHASP), Remedial Action Plan (RAP) and Site Management Plan (SMP) for site remediation, excavation, redevelopment, and post development. These plans will include detailed procedures for managing both known contamination issues (e.g., tank removal, and soil and groundwater remediation of existing petroleum spills, excavation, and removal of existing septic tanks or fields, floor drains, and

historic fill) and any unexpectedly encountered contamination issues. The CHASP will also include monitoring necessary to ensure that dust control procedures are effective.

- Requirements for vapor barriers and sub-slab venting systems in new buildings, where remaining subsurface contamination could otherwise lead to unacceptable exposure inside buildings, would also be incorporated into the overall development program.

The (E) designations that were previously placed on lots in the District (and, potentially, BCP requirements, should the developer choose to participate in the BCP), would serve as institutional controls to ensure implementation of the above measures and any necessary post-construction measures, e.g., Site Management Plans that describe health and safety procedures during subsurface utility repair.

LOT D AND LOT B

Lot D is a paved parking lot with a small fenced area for trash collection. Tires and empty 35-gallon drums were noted. Evidence of a potential underground storage tank was observed (an apparent fill and vent pipe). The August 2008 Phase I ESA found no historic or current petroleum storage tanks registered on the site. The overall site was not listed on any of the reviewed federal, state or local regulatory databases. Prior to development of Lot D, a Phase II ESA would be performed to assess potential contamination and assist in preparation of any necessary remedial plan and construction health and safety procedures.

Information on Lot B was based on a subsurface investigation conducted in 1998 and on subsequent environmental investigations relating to the development of CitiField. In 2006, two soil borings (retrofitted with groundwater monitoring wells) and 12 soil gas (methane) samples were collected. Fill material included coarse-to-fine sand and gravel, silt, mica, cinders, wood, roots, glass, brick, metal, and asphalt overlying marsh deposits. The soil sampling did not identify significant contamination (the results were consistent with those generally found in historical fill materials in New York City). Similarly, the groundwater sampling identified some levels (generally of metals) above the most stringent (drinking water) standards but these were consistent with the fill. The soil gas sampling found elevated levels of methane (most likely attributable to the marsh deposits and potentially material placed during the filling).

To avoid the potential for significant adverse effects at Lots D and B, the 2008 FGEIS outlined the RAP/CHASP procedures that would be followed prior to and during construction including:

- Proper handling and disposal of all materials requiring off-site disposal, including historic fill materials and any unexpectedly encountered contaminated materials.
- Monitoring of all excavation for the presence of tanks, drums, or soil that shows evidence of potential contamination.
- Air monitoring (for volatile organics, methane, and particulates) during construction.
- Protocols for reporting spills or other concerns to relevant governmental agencies.
- Contingency and emergency response plans.
- Dust control measures would be implemented during all earth-disturbing operations. Water would be available on-site for sprinkling/wetting to suppress dust in dry weather or as necessary. Water would be used to suppress dust on haul roads and to wet equipment and excavation faces if that was found to be an issue. Stockpiled excavated material would be securely covered with tarps or plastic sheeting to prevent dust or run-off.
- SWPPPs to address the control of erosion and stormwater runoff from construction.

Willets Point Development

- Installation of appropriate systems to prevent the migration of vapors into any newly constructed buildings.

Institutional controls, specifically development agreements and/or modification of the existing leases for these lots, would ensure implementation of the above measures and any necessary post-construction measures, e.g., Site Management Plans that describe health and safety procedures during subsurface utility repair.

C. METHODOLOGY

The information used in this chapter included the information gathered for the District as part of the 2008 FGEIS, available additional data from one additional subsurface investigation within the District (at Block 1822, Lot 17) and a review of an updated (February 2013) regulatory database for the District. It is anticipated that no substantive changes within the District have occurred since the 2008 FGEIS. Although various businesses have closed since the 2008 FGEIS, no extensive cleanup has occurred, and subsurface conditions are not expected to have changed significantly. In December 2012, a Phase I ESA was prepared by Integral Consulting, Inc. addressing the Willets West and South Lot portions of the project site. A February 2006 *Phase II Subsurface Investigation*, prepared by AKRF Inc. for the Shea Stadium Redevelopment project, included the results of soil analyses and soil gas sampling within the footprint of the Willets West project area. A March 2011 *Site Investigation Findings Report* (related to potential project infrastructure improvements) conducted by Environmental Planning & Management, Inc. (EPM) included three additional locations with soil, groundwater and/or soil gas sampling within the footprint of the Willets West project area.

D. EXISTING CONDITIONS

As noted above, existing conditions at the District, Lot B, and Lot D portions of the project site are not expected to have changed significantly from those summarized in the 2008 FGEIS. Consistent with the earlier findings, the Phase II ESA conducted at Block 1822, Lot 17 identified soil and groundwater contamination in proximity to the location of former underground fuel and gasoline tanks, and consistent with contamination usually found in fill materials. Polychlorinated biphenyls (PCBs) were found in one of the soil samples; these compounds can be associated with automotive wrecking as well as electrical transformers. It is possible that all or some portion of the District would be entered into the BCP. Review of the updated regulatory database for the District identified concerns similar to those noted in the 2005 Phase I ESA, including automotive repair shops, wrecking and salvage facilities, junk yards and waste processing facilities with numerous past or present petroleum storage tanks. One minor active-status spill was reported to NYSDEC within the District in 2012. More than 200 spills were reported to NYSDEC within the District and assigned a closed status. The spill listings noted that some remediation of the individual releases had been conducted, but residual contamination may remain, and that subsurface contamination exists throughout the District.

The December 2012 Phase I ESA performed for the Willets West and South Lot portions of the project site identified that these properties were part of the much larger “ash dump” in the early part of the 20th century. As described above, the Willets West area was paved around 1950 and used for parking until 1964, when Shea Stadium opened on the property. The South Lot has been used as for parking since the mid 1960s. In 2009, Shea Stadium was demolished, the site was paved, and the Willets West area has since been used for parking with multiple small ticketing structures. The Phase I ESA found no evidence of historical or current petroleum storage tanks

or other on-site historical uses of concern. Nearby uses include an MTA rail yard. The February 2006 Phase II Subsurface Investigation included four soil borings and five soil gas samples within the Willets West footprint. The eight-foot-deep soil borings all encountered fill material throughout their depth. Laboratory results of soil samples were consistent with historical fill materials, with no evidence of petroleum contamination. Three out of the five soil gas samples had elevated methane levels. The March 2011 Site Investigation Findings Report indicated similar soil results. The one soil gas sample showed both elevated levels of methane and some low levels of volatile organic compounds. Groundwater laboratory analysis results were consistent with typical urban fill sites with no evidence of petroleum contamination; however, the groundwater at one location was noted to have a petroleum sheen and odor.

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

Without the proposed project, neither the District nor the other properties comprising the project site are anticipated to experience substantial change. In the event that projects independent of the proposed project were to occur, such development would not be expected to result in significant adverse impacts with respect to hazardous materials. In the No Action scenario, the Special Willets Point District portion of the project site would have both continued NYSDEC involvement (related to spill cleanup and enforcement actions) and New York City Office of Environmental Remediation (OER) involvement related to the existing (E) designations. For portions of the sites outside of the District, any future development would be subject to new City leases and/or disposition agreements which would set forth hazardous materials requirements, similar to those associated with the proposed project (see Section F, “Probable Impacts of The Proposed Project”), but tailored to the development (e.g., extent of proposed soil disturbance and land use).

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

Construction of the proposed project would involve demolition of all existing structures on the project site (some of which are believed to contain LBP, ACMs, and PCB-containing electrical components) and a variety of earthmoving/excavating activities that would encounter subsurface contamination (e.g., petroleum, solvents or PCBs), particularly within the District. The project site is within the Federal Emergency Management Agency (FEMA) 100-year floodplain, and thus in some locations, particularly within the District, new fill would be required to grade and raise the project site structures above the 100-year floodplain level, consistent with the New York City Building Code. Changes to the grade elevation are expected to occur in phases. During Phase 1A the majority of the project site will remain at the existing grade and only the hotel and commercial spaces would be built at a higher grade above the floodplain elevation. The remainder of the extent of Phase 1A and 1B would be raised above the floodplain elevation prior to completion of the development of Phase 1B in 2028. Those grade changes will either occur through new fill and retaining walls or by building atop basements that raise the finished floor height above the floodplain elevation. Grade transitions would be created between the new streets in Phase 1B and the existing street grades that would remain in the Phase 2 area until that area is raised prior to completion of Phase 2 development in 2032.

To avoid the potential for significant adverse impacts related to hazardous materials, the proposed project would include appropriate health and safety (e.g., dust control and air monitoring) and investigative/remedial (e.g., delineating and excavating contaminated soils and disposing of them off site at an appropriately licensed facility) measures that would precede or

Willets Point Development

govern both demolition and soil disturbance activities. These measures would be conducted in compliance with all applicable laws and regulations and would conform to appropriate engineering practices. Also, given that some subsurface contamination would likely remain after completion of construction (e.g., historical fill materials underlying the development area) and in nearby areas that would not be cleaned up until a subsequent phase of development, new development would require engineering controls, which could include capping to prevent exposure to underlying soils, groundwater controls at construction site boundaries (pile driving for new construction would not be anticipated to significantly change the overall groundwater flow regime), and vapor barriers with active or passive sub-slab depressurization systems beneath enclosed or occupied buildings (e.g., not open parking structures). As development of the District is contemplated to occur in phases, excavation and cleanup during Phase 1B and Phase 2 would occur near already developed buildings and uses, requiring stringent controls on construction dust and other potential sources of contaminant migration. The same issues were addressed (albeit for a slightly smaller initial development area) and the same conclusions reached (i.e., significant adverse impacts would be avoided) in Technical Memorandum #4 which assumed an undeveloped “buffer area” adjacent to the initial development area. Institutional controls would be used to ensure the investigations and remedial measures would be implemented along with requirements to prevent future exposure during intrusive work and subsurface utility repairs at developed sites. Specifically, these institutional controls would be the existing (E) designations (possibly supplemented by additional requirements should the developer choose to participate in the BCP for any lots) for the District, and restrictions added to the proposed lease amendment for the remainder of the project site.

The institutional controls would require the project sponsor, prior to seeking or obtaining DOB permits associated with redevelopment, conduct Phase I and Phase II ESAs (to the extent they have not already been conducted), necessary remediation (with appropriate construction-related HASPs) either prior to or as a part of site development, to the satisfaction of (for the District) the OER or (for lots outside of the District) the New York City Department of Environmental Protection (DEP)¹. A Phase II Subsurface Investigation Work Plan and a Health and Safety Plan (HASP) ~~were have been~~ prepared for the Willets West portion of the project site in February 2013 and submitted to DEP for review and approval. The Phase II Work Plan and HASP were revised and resubmitted to DEP in June 2013 based on a DEP letter requiring additional testing (dated March 27, 2013), and the revised Work Plan and HASP were approved by DEP in a letter dated July 31, 2013. Should all or portions of the District be entered into the BCP, this State program would entail similar requirements to OER’s (which would not be superseded). The BCP is a voluntary program in which a property owner/developer enters into an agreement with the State to conduct investigation and remediation in accordance with a variety of requirements, including public participation. Following the cleanup, with, if required, the implementation of deed restrictions to ensure the performance of institutional and engineering controls, the State issues a Certificate of Completion indicating cleanup has been achieved consistent with the proposed site use. It is not anticipated that cleanup requirements of the State and City would differ substantively. Likely components of site remediation and other measures to avoid impacts are essentially unchanged from those described in Chapter 12 of the 2008 FGEIS, i.e., they may include:

¹ The project sponsor does not currently have site control of Willets West and South Lot; prior to commencement of construction, project sponsor will perform appropriate testing on these sites as required.

- Procedures for pre-demolition removal of asbestos and appropriate management of LBP and PCB-containing equipment.
- Additional subsurface investigation, both within the District and of areas not yet investigated, to better characterize soils to be removed for excavation.
- Development of a CHASP and SMP for site remediation, excavation, and redevelopment that would include detailed procedures for managing both known contamination issues (e.g., tank removal, and soil and groundwater remediation of existing petroleum spills, excavation, and removal of existing septic tanks or fields, floor drains, and historic fill) and any unexpectedly encountered contamination issues. The CHASP would also include procedures for avoiding the generation of dust that could affect the surrounding community (especially at later-phase sites neighboring already developed sites), as well as the monitoring necessary to ensure that no such impacts occur.
- Prevention of contaminant migration to a particular development site from other properties might entail the use of various forms of groundwater flow controls at construction site boundaries and/or vapor barriers and sub-slab venting systems could be incorporated into the foundations of new buildings to prevent remaining subsurface contaminated vapors from entering buildings. Procedures that are instituted would be consistent with applicable laws and regulations.
- A cap of imported clean soil may be placed uppermost in landscaped areas and other areas not covered by buildings, paving or other impermeable surfaces.

Institutional controls (specifically, [E] designations, restrictions added to leases, or BCP requirements, should the developer choose to enroll in the BCP) would be used to ensure required post-development procedures (e.g., implementation of health and safety procedures during subsurface utility repair) would be implemented. Methods for guaranteeing the continued effectiveness of these controls would include periodic (e.g., annual) certification and reporting requirements.

CONCLUSIONS

Contamination in the subsurface (including petroleum contamination) within the District has been identified through limited Phase II ESAs. This contamination is likely related primarily to the District's current and historical automotive-related businesses. Although detailed investigations have not yet been performed at the other portions of the project site, less extensive contamination has been found and is anticipated to be encountered, with levels (including elevated methane levels) expected to be consistent with the area's historical ash filling. In addition to subsurface contamination, asbestos-, LBP-, and PCB-containing equipment are likely to be present inside existing buildings.

With the implementation of the variety of measures described above, not only would no significant adverse impacts related to hazardous materials be expected to occur as a result of construction or operation of the proposed project, but the proposed project, with its associated extensive cleanup which would otherwise likely not occur at all or only much more slowly, would result in significant potential benefits to public health and the environment. To ensure the various required measures would be implemented, they would be made binding on all site developers through (E) designations and conditions in the development agreements and/or amended leases. The provisions of the development agreements and/or amended lease agreements, relating to the substance and enforceability of these commitments, would be subject to approval by the lead agency in consultation with DEP. Although some hazardous materials

Willeys Point Development

would likely remain in the subsurface following construction of the proposed project, with the building vapor control measures outlined above, there would be no exposure pathways and thus no further potential for significant adverse impacts. Thus, consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the proposed project would not result in significant adverse impacts related to hazardous materials. *

A. INTRODUCTION

This chapter assesses whether any changed background conditions or the differences between the reasonable worst-case development scenario (RWCDS) and the program assessed in the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda would result in any significant adverse impacts on water and sewer infrastructure that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

This analysis finds that the proposed project would not result in significant adverse impacts to water and sewer infrastructure that were not addressed in the 2008 FGEIS and subsequent technical memoranda. Infrastructure improvements would be required for various phases of the project, as detailed in this section:

PHASE 1A

New 12-inch water mains in 35th Avenue, 126th Street, 127th Street, and Willets Point Boulevard would be constructed as necessary to support the proposed development. For Willets West, a new on-site water loop would be required to tie into existing water main in Roosevelt Avenue.

Sanitary sewer infrastructure, either existing or being built by the New York City Economic Development Corporation (EDC), would be adequate to accommodate the Phase 1A development. A 36-inch sanitary sewer, as well two stubbed connections in 126th Street: one 24-inch and one 16-inch, is currently being constructed by EDC. As a part of the proposed project, the 16-inch connection would be extended south along 126th Street by the Queens Development Group, LLC (QDG). Based on current estimates, the 36-inch sanitary sewer under construction, the 24-inch sewer downstream from it, and the 37th Avenue pump station would have sufficient capacity to accommodate the development proposed under Phase 1A. As part of the Phase 1A DEP approval process, QDG would work with the New York City Department of Environmental Protection (DEP) to assess the operations of the existing pump station. Based on this assessment, QDG would replace or upgrade components identified as requiring such work as a result of the additional flows associated with the Phase 1A development. Based on measured existing flow to the Bowery Bay Water Pollution Treatment Plant (WPTP) and the projected sanitary flow from the proposed development in Phase 1A, the WPTP would have sufficient capacity to accommodate the proposed project flow.

A 7.5-by-5-foot box storm sewer currently under construction by EDC would be extended south along 126th Street by QDG as part of the proposed project to accommodate Phase 1A development within the Special Willets Point District. For Willets West and the other sites, existing infrastructure would be sufficient to convey stormwater runoff.

PHASE 1B

Consultation with DEP would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required to support the Phase 1B development. As assumed in the 2008 FGEIS, the existing 72-inch water main within Willets Point Boulevard would remain in place and a permanent easement, mapped on the City map, would be provided to enable DEP access to this water main. A grade change and replacement of portions of the water main, contemplated in Technical Memorandum #4 would not be required.

Based on current estimates, the 36-inch sanitary sewer currently under construction would have sufficient capacity to accommodate the development proposed under Phase 1B. Upgrades to the 37th Avenue pump station and its force main would likely be required for Phase 1B development. If needed to support Phase 1B development, QDG would fund the 37th Avenue pump station upgrade, at the time when the need arises. It is anticipated that the upgrade would occur within the existing city land or rights-of-way. Verification of this requirement by DEP will be obtained prior to Phase 1B development. Based on measured existing flow to the Bowery Bay WTP and the projected sanitary flow from the proposed development through Phase 1B, the WTP would have sufficient capacity to accommodate the proposed project flow.

Stormwater and sanitary sewer infrastructure constructed would be sized in accordance with the DEP-approved amended drainage plan (ADP) prepared by QDG.

PHASE 2

For the District, consultation with DEP would be required to determine water supply requirements for Phase 2 of the proposed project. Additional internal water service would likely be required to support the proposed development in 2032. Additionally, consultation with DEP would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required to support the Phase 2 development, if not already constructed in a prior phase. For all other sites, water service would remain as constructed.

For the District, new sanitary sewer trunk mains would be required in Northern Boulevard 126th Street, and Roosevelt Avenue. These sewers would be sized in accordance with the ADP that would be developed. Based on current estimates, the 36-inch sanitary sewer currently under construction would have sufficient capacity to accommodate the development proposed with the full development through Phase 2. Per the draft ADP, upgrades to the 37th Avenue pump station and its force main would be required for Phase 2. Specifically, the operating capacity of the 37th Avenue pump station (currently 3,450 gpm) would need to be upgraded to 8,400 gpm. If not previously performed upgrades to the 24-inch sewer under the Grand Central Parkway, the 37th Avenue pump station and its associated downstream force main would be required, and would be funded by the developer of Phase 2. These upgrades would be in conformance with the DEP approved ADP. Based on measured existing flow to the Bowery Bay WTP and the projected sanitary flow from the proposed development through Phase 2, the WTP would have sufficient capacity to accommodate the proposed project flow.

For the District, new storm sewers would be required in Northern Boulevard, 126th Street, and Roosevelt Avenue. These sewers would be sized in accordance with the ADP developed for Phase 2. In addition, a 60-inch outfall would be required in 127th Street for Phase 2.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS found that although the Willets Point Development Plan would have generated new demands on infrastructure, the municipal systems serving the District and surrounding area, as enhanced as part of the Willets Point Development Plan, would have adequate capacity to meet the needs of the Willets Point Development Plan as well as the potential future development on Lots B and D. These conclusions did not change in subsequent technical memoranda, although the specific enhancements were modified based on further analysis and discussion with DEP.

WATER SUPPLY

The 2008 FGEIS and subsequent technical memoranda assumed that new local water supply distribution lines would be provided by the developer(s) to the blocks in the southwestern portion of the District, and uses in the eastern portion of the District would continue to be served by existing supply lines. This infrastructure would be built as private infrastructure, constructed to meet DEP standards.

The 2008 FGEIS assumed that the existing 72-inch pre-stressed reinforced concrete pipe (PRCP) water main within Willets Point Boulevard would remain in place and that the developer(s) would provide a permanent easement mapped on the City map in order to provide acceptable access to the existing main. The width and designation of this easement was to be determined in consultation with DEP and in accordance with DEP requirements. In Technical Memorandum #4, as a result of discussions with DEP, this assumption was revisited and the memorandum examined the potential replacement of portions or all of the 72-inch water main. In this scenario, Willets Point Boulevard would have been raised to flood plain elevation and the water main would have been repositioned higher in the street bed. The analysis provided in Technical Memorandum #4 found that there would be no interruptions in service and no significant adverse impacts would result from the potential water main replacement.

The 2008 FGEIS estimated that the Willets Point Development Plan and the potential future development on Lots B and D would increase water demand by approximately 4.36 million gallons of water per day (mgd) and concluded that this additional demand would not result in a significant adverse impact on the City's water supply system. Subsequent memoranda recalculated water demand, and found that the effects would be the same as described in the 2008 FGEIS.

SANITARY SEWAGE

The 2008 FGEIS and subsequent technical memoranda describe how the District has no connection to the City's sanitary sewer system. It was assumed that under the Willets Point Development Plan, the District would be connected to the City's sanitary sewer system, to eliminate the District's reliance on septic tanks. Improvements would include new sewers and new connections to the existing 96-inch-diameter combined sewer in 108th Street. The 2008 FGEIS and Technical Memoranda #1 through #3 assumed construction of a new pump station (most likely to be located within the District) and force main to make this connection; As a result of DEP guidance, a gravity flow system was used instead. Technical Memorandum #4 incorporates those changes.

The 2008 FGEIS and subsequent technical memoranda also considered potential effects on the 37th Avenue pump station, and determined that the pump station does not have adequate

Willets Point Development

capacity for the full build out of the District. In 2010, EDC commissioned a study to assess the adequacy of the pump station for development of Phase 1 (the program for Phase 1 at the time was different in extent and use from the currently proposed Phase 1A and Phase 1B). The study also considered existing sanitary flows from CitiField and the residential district tributary to the pump station. The study concluded that the pump station did have sufficient capacity to accommodate the Phase 1 development, and DEP concurred with the conclusion.¹

The 2008 FGEIS estimated that the Willets Point Development Plan and the potential future development on Lots B and D would have resulted in an increase of sanitary flow to the Bowery Bay Wastewater Treatment Plant (WWTP) of approximately 2.8 mgd and concluded that the Bowery Bay WWTP would have adequate capacity to meet the increased demand associated with the Willets Point Development Plan. Subsequent memoranda (Technical Memoranda #3 and #4) also calculated increases in sanitary flow and resulted in the same conclusions related to the Bowery Bay WWTP.

STORMWATER

The 2008 FGEIS and subsequent technical memoranda identified the need for the following, related to stormwater:

- Prior to redevelopment of the site, an ADP would be prepared by the developer to comprehensively address all the surface stormwater runoff and separate handling of the dry weather flow that would be generated as a result of the Willets Point Development Plan, and drainage features to be included in the development of the District. The approved ADP would accommodate the City's current drainage plan for the area, and easements associated with highway drainage, and would be subject to prior review and approval by DEP.
- The 2008 FGEIS found that the overall stormwater runoff in the future with the Willets Point Development Plan would have remained largely unchanged from the then existing runoff volume of 366 cubic feet per second (cfs) as there would be no substantial change in surface coverage on the site. The 2008 FGEIS also identified the need for a new stormwater conveyance system to address inadequate stormwater management conveyance systems within the District, as follows: a lack of detention prior to discharge at two outfalls on 126th and 127th Streets; stormwater runoff greater than the allowable flow per the current drainage plan at the two outfalls; and inadequate sizing of the conveyance system, resulting in uncontrolled and untreated runoff and street flooding during storm events. To eliminate these stormwater management issues, the Willets Point Development Plan indicated a need for the construction of a new stormwater conveyance system, including piping, sustainable design features, and an adequately sized detention tank, or other equivalent means to accommodate the stormwater that would be beyond the discharge capacity of the two stormwater outfalls serving the District. The 2008 FGEIS also identified a potential need to construct a new outfall to augment the then-existing system. As part of the ongoing infrastructure work in support of development within the District, planning and construction has progressed to increase the capacity of the stormwater outfall at 126th Street (see "Existing Conditions," below).

¹ Memorandum regarding Willets Point Development 37th Ave Pumping Station from DEP, dated December 20, 2010, and signed by Stella Rozelman, P.E., Chief of Division of Collection Facilities, Engineering Analysis and Planning.

- In Technical Memoranda #3 and #4, which examined development of in phases, it was concluded that flooding would continue in the undeveloped portions of the District until the District-wide stormwater management features were implemented.
- The stormwater management plan would be reviewed and approved by DEP and would specify Best Management Practices (BMPs) and sustainable design features that the project would include. Technical Memoranda #3 and #4 identified that the stormwater management plan would be implemented in stages.
- The 2008 FGEIS identified the need for stormwater to be pre-treated prior to discharge to Flushing Bay, which is a regulated water body, to ensure that applicable discharge criteria would be met after construction is completed. Stormwater discharge to Flushing Bay will be treated in accordance with New York State Department of Environmental Conservation (NYSDEC) and DEP regulations.
- The 2008 FGEIS concluded that implementation of the Willets Point Development Plan would require approval pursuant to the State Pollutant Discharge Elimination System (SPDES) general permit program for stormwater discharges from construction activities, as well as post construction (Build) conditions. Prior to initiation of construction activities, a Stormwater Pollution Prevention Plan (SWPPP) would be developed pursuant to the requirements of the general permit and would be enforced throughout the sequence of construction activities and after construction is complete.

COMBINED SEWER OVERFLOWS

The 2008 FGEIS anticipated that development within the District would provide separate storm sewers. Therefore, stormwater runoff would not contribute to flow being directed to the Bowery Bay WWTP. However, since an increase in sanitary flow could impact Combined Sewer Overflow (CSO) discharges, the effect of an increase in sanitary flow to the combined sewer/regulator system within the Bowery Bay WWTP service area was investigated using Wallingford Software's InfoWorks model. Based on the simulations, the 2008 FGEIS and subsequent technical memoranda concluded that there would be no significant increase in the volume or frequency of CSO events as a result of the Willets Point Development Plan, and no significant effect on the water quality.

C. METHODOLOGY

This chapter has been prepared in accordance with the guidelines of the 2012 *CEQR Technical Manual*. It describes existing conditions and future conditions without the proposed project, and analyzes the probable impacts that the proposed project may have on water and sewer infrastructure. This analysis assesses future conditions in 2018, 2028, and 2032, when completion of Phase 1A, Phase 1B, and Phase 2 (full buildout) of the proposed project are anticipated, respectively.

D. EXISTING CONDITIONS

Information in this section is based on the 2008 FGEIS, subsequent technical memoranda, and information provided by Langan Engineering, Environmental, Surveying, and Landscape Architecture, D.P.C. (Langan), the engineer for Phase 1A of the proposed project. It also describes infrastructure improvements currently under construction within the District and surrounding area. In general, these improvements consist of new sanitary and stormwater mains that will provide new public sanitary sewer service to the existing uses as well as to support the redevelopment of the District and adjacent areas, and replace an inadequately-sized stormwater

Willets Point Development

sewer and outfall to help alleviate chronic flooding that occurs in the District and adjacent areas. Sizing for the sewer improvements is based on a draft ADP developed by EDC. EDC broke ground on these improvements in December 2011.

WATER SUPPLY

SPECIAL WILLETS POINT DISTRICT¹

The District and adjoining streets currently have a complete, interconnected grid of water distribution mains along Northern Boulevard, 34th Avenue, 126th Street, 126th Place, 127th Street, and Willets Point Boulevard. This gravity distribution system is fed by City Water Tunnel No. 2.

Existing demands within the District are generally limited to the current on-site uses and met by two 12-inch water mains that pass under the Grand Central Parkway. There is an existing 72-inch water main that passes through the site along Willets Point Boulevard that supplies water to a substantial portion of northeast Queens. There are no connections to the 72-inch water main within the Willets Point District.

As planning for the District has evolved since the 2008 FGEIS, modifications with respect to some of the proposed infrastructure elements have been considered (see discussion above). It is currently assumed that the existing 72-inch water main beneath Willets Point Boulevard would remain in place.

EDC is also upgrading a portion of the water main in 126th Street between Northern Boulevard to a point just south of 35th Avenue. This work is a part of the EDC contract to construct a new storm sewer in 126th Street.

WILLETS WEST

The Willets West portion of the project site comprises an approximately 30.7-acre section of the surface parking field adjacent to CitiField.

A 12-inch water main runs east-west within Roosevelt Avenue to the south of the Willets West portion of the project site; another 12-inch water main runs east-west just north of Shea Road, to the north of the Willets West portion of the project site. CitiField currently maintains a series of 8-inch water mains on site that run to the east of the Willets West portion of the project site and to the north of Lot B and connect to the existing water mains in Shea Road and Roosevelt Avenue.

SOUTH LOT AND LOT D

The South Lot and Lot D parking lots are collectively approximately 12.1 acres in area. Lot D and the South Lot are used for commuter parking and parking for United States Tennis Association (USTA) National Tennis Center (NTC) events when baseball games are not in progress.

¹ The Special Willets Point District is within the boundary of the federally designated Brooklyn-Queens sole source aquifer. This designation was made pursuant to Section 1424 (e) of the Safe Drinking Water Act (SDWA), in recognition of the importance of the aquifer's vulnerability to contamination. As discussed in the 2008 FGEIS, the area's reliance on septic disposal inherently conflicts with SDWA goals. The aquifer is currently not used as a potable water source.

According to DEP maps, South Lot and Lot D are served by the 12-inch water main in Roosevelt Avenue and an 8-inch water main that runs through the site. The 72-inch water main runs along the southern property line of the two lots.

LOT B

Lot B, which is approximately 4.7 acres in area, is used for VIP/ADA parking by CitiField. There is water service around Lot B, including the 12-inch water main in Roosevelt Avenue and additional water service along the north of Lot B.

WATER DEMAND

Currently, the only water usage on the project site is within the District, with a demand of 159,964 gallons per day (gpd) of water (see **Table 11-1**).

Table 11-1
Existing Water Demand

Use	Size	Demand Type	Rate	Consumption (gallons per day)
Residential	1 (person)	Domestic	100 gpd/person	100
		Air Conditioning	N/A	0
Commercial/Office	194,567 sf	Domestic	0.10 gpd/sf	19,458
		Air Conditioning	0.17 gpd/sf	33,076
Retail	39,230 sf	Domestic	0.24 gpd/sf	9,415
		Air Conditioning	0.17 gpd/sf	6,669
Industrial ¹	337,949 sf	Domestic	0.10 gpd/sf	33,795
		Air Conditioning	0.17 gpd/sf	57,451
Total				159,964
Note: 1. No rate provided in <i>CEQR Technical Manual</i> for Industrial uses therefore Commercial/Office rate was used. Source: Rates from the 2012 <i>CEQR Technical Manual</i> .				

SANITARY SEWAGE

New York City's sewer system includes an extensive grid of sewers beneath the streets that convey wastewater to 14 WWTPs. Together, these plants, which are operated by DEP, treat approximately 1.7 billion gallons of sewage per day. Most of the sewer systems within New York City are combined sewer systems, which carry both sanitary sewage from buildings and stormwater collected in catch basins and storm drains. However, some areas of the City, primarily in Queens and Staten Island, have separate systems for sanitary sewage and stormwater. In addition, small areas of Staten Island, Brooklyn, and Queens, including the District, use septic systems to dispose of sanitary sewage.

The project site is within the service area of the Bowery Bay WWTP, which is located on the East River in Astoria, Queens. The Bowery Bay WWTP treats sanitary wastewater to secondary treatment standards prior to discharge to the East River. The existing sewer system within the Bowery Bay WWTP service area is a combined sewer system that collects both sanitary sewage and stormwater runoff. Discharges from this plant are regulated by NYSDEC through a SPDES permit. At the plant, water is treated through a variety of physical and biological processes that remove solid contaminants so that the water discharged into the City's waterways does not adversely affect water quality. During dry weather, combined sewers function as sanitary sewers, conveying all flows to the WWTP for treatment. During wet weather, however, stormwater entering the combined sewer/regulator system can exceed the capacity of the regulator and the treatment plant and trigger a CSO event into the City's waterways. The

Willets Point Development

purpose of a regulator is to divert sanitary flow from the existing combined sewers to the intercepting sewer during normal flow periods (dry weather), and limit the flow to the intercepting sewer to twice the dry weather flow during storm periods (wet weather). During a significant storm event, CSOs within the Bowery Bay WWTP service area discharge to the East River and Flushing Bay. See “Combined Sewer Overflows,” below.

The combined sewer/regulator system within the Bowery Bay WWTP service area is designed to deliver twice the mean dry weather, or sanitary, flow to the Bowery Bay WWTP for treatment. While the total hydraulic capacity of the Bowery Bay WWTP is 300 mgd, it can only provide treatment to secondary levels for 150 mgd. Flow records for the plant are maintained by DEP and are reported to NYSDEC. The Bowery Bay WWTP, which has a permitted design capacity of 150 mgd, experienced flows of 112 mgd in October 2012 with a 12-month running average flow of 111 mgd.

SPECIAL WILLETS POINT DISTRICT

As described above, the District is located within the service area of the Bowery Bay WWTP; however, as detailed in the 2008 FGEIS, the Willets Point area is not connected to the New York City sanitary sewer system and relies entirely on septic systems as the means of sewage disposal.

Currently, the 24-inch gravity sewer that runs underneath the Grand Central Parkway is the nearest DEP sewer network connection to the District. The farthest eastern extent of this network is a manhole located approximately 100 feet to the west of CitiField’s western property line. The 24-inch sewer drains to the 37th Avenue pump station. As detailed in the 2008 FGEIS, this pump station has the capacity to pump up to 5 mgd into a 20-inch force main, which discharges into a 36-inch gravity sewer at the intersection of 37th Avenue and 111th Street. The 36-inch sewer drains to the 96-inch combined sewer in 108th Street (see **Figure 11-1**).

Since the issuance of the 2008 FGEIS, EDC has funded the construction of a 36-inch PRCP gravity sewer that is currently being built across the breadth of CitiField’s northern and western parking lots. The 36-inch sewer was designed to accept flow from the District. Once this work is completed, the District could be connected to the DEP sewer network. This connection would be made to the existing 24-inch gravity sewer which crosses beneath the Grand Central Parkway and would convey flow to the existing 37th Avenue pump station.

In connection with this new sanitary sewer, a new 24-inch Class III PRCP sanitary sewer stub is also under construction on 126th Street extending from the 36-inch gravity sewer north towards 34th Avenue, as is a short 16-inch sanitary sewer stub south along 126th Street.

WILLETS WEST

The Willets West portion of the project site is located within the service area of the Bowery Bay WWTP and is served by sanitary sewers. The nearest connection to the City sanitary sewer network is the 24-inch sewer that is located west of Citi Field, beyond the perimeter of the park road system.

CitiField currently maintains a 12-inch sanitary force main that connects to this 24-inch sewer, which drains to the 37th Avenue pump station. This pump station has a rated capacity of 3,460 gallons per minute (gpm) and drains to a 20-inch force main. Sanitary flow from the 37th Avenue pump station drains to the Bowery Bay WWTP through the CSO network in 108th Street.

SOUTH LOT AND LOT D

The South Lot and Lot D portions of the project site are located within the service area of the Bowery Bay WWTP; however, there does not appear to be any existing sanitary sewer service within the public roadways surrounding the site. The MTA station drains to an on-site individual subsurface sewage treatment system (septic) that is located in Lot D.

LOT B

The Lot B portion of the project site is located within the service area of the Bowery Bay WWTP. The existing CitiField sanitary force main is located near Lot B. The MTA station drains to an on-site individual subsurface sewage treatment system (septic) that is located in Lot B.

SANITARY SEWAGE CALCULATION

For the purposes of this analysis, the amount of sanitary sewage is conservatively estimated as all water demand from the project site except that used by air conditioning, which is typically not discharged to the sewer system. Current uses within the District generate an estimated 62,767 gpd of sanitary sewage, which is discharged to septic systems (all other portions of the project site do not generate any sanitary sewage).

STORMWATER

Stormwater runoff volumes and rates of discharge vary depending upon the type of land, cover, and slope.

SPECIAL WILLETS POINT DISTRICT

As described in the 2008 FGEIS, stormwater runoff generated in the District is discharged into Flushing Bay via two 60-inch outfalls on 126th Street and 127th Street without detention, resulting in surcharge and flooding conditions. The maximum capacity for each outfall is 74 cfs. The 2008 FGEIS identified that the runoff generated in existing conditions is greater than the allowable flow tributary to the two outfalls (148 cfs), indicating that the stormwater discharge infrastructure is inadequate. In addition, there is only minimal stormwater conveyance infrastructure, and a portion of the District is below a sufficient grade to allow for gravity conveyance of stormwater toward the outfalls. Since the area lacks an adequate drainage system, much of the runoff flows as overland flow and ponds, causing area streets to flood during storm events. Furthermore, runoff from the many facilities in the area is neither controlled nor treated prior to entering the storm drains that convey this stormwater to the outfalls.

As part of the ongoing infrastructure work in support of the redevelopment of the District, planning has progressed to increase the capacity of the stormwater outfall at 126th Street, construct a new 7.5-by-5-foot storm sewer in a portion of 126th Street, and to better manage stormwater within the District. A Joint Application for Permits was submitted to NYSDEC and the United States Army Corps of Engineers (USACE) on November 4, 2010 for the replacement of the 126th Street storm sewer outfall. The USACE issued authorization to EDC for the replacement of the 126th Street outfall in December 2010. A NYSDEC permit for construction of the outfall improvements was issued on February 3, 2011. The improvements consist of the replacement of the storm sewer water-ward of the concrete cut-off wall under the existing New York City Department of Parks and Recreation's (DPR) esplanade along Flushing Bay. The new 126th Street outfall, combined with the re-use of the existing 127th Street outfall, will provide

Willets Point Development

sufficient capacity to manage stormwater runoff from the District, when redeveloped, as indicated in the permit application for the Willets Point Off-site Sewer Improvement Project.

The new 7.5-by-5-foot storm sewer in 126th Street is currently under construction and will discharge to Flushing Bay via the new storm outfall that is also under construction. This storm sewer will extend along 126th Street from the outfall, south to between 34th and 35th Avenues.

WILLETS WEST

A 72-inch New York State Department of Transportation (NYSDOT)/DPR storm sewer, which drains to Flushing Bay (see **Figure 11-1**), is present in the Willets West portion of the project site. The outfall to Flushing Bay is not associated with the DEP stormwater outfalls in 126th and 127th Streets. The parking lots west of CitiField (including the Willets West area), the perimeter roadway (Shea Road), and a majority of the stadium drain to this 72-inch sewer. The majority of the runoff tributary to this storm sewer is treated via subsurface BMPs. Some areas discharge untreated stormwater and are in violation of current NYSDEC regulations; however, no detention is provided or needed for discharge to a NYSDOT sewer.

SOUTH LOT AND LOT D

Stormwater from the eastern portions of Lot D currently drains to a 54-inch storm sewer in 126th Street before being discharged into Flushing Bay via a 60-inch outfall on 126th Street.

Stormwater from the South Lot and possibly from the western portion of Lot D drains to a NYSDOT and DPR storm sewer network that drains to two 22-foot by 10-foot DEP CSOs that discharge directly to Flushing Bay via outfall BB006. Based on discussions with DPR, surface ponding of stormwater runoff is prevalent on South Lot and Lot D after rain events.

LOT B

Stormwater runoff from the Lot B portion of the project site currently is detained, treated, and directed to the 54-inch DEP storm sewer in 126th Street before being discharged into Flushing Bay via a new 60-inch outfall on 126th Street.

STORMWATER CALCULATIONS

Table 11-2 provides information on the surface-type distribution of the project site. The weighted runoff coefficient is also calculated for each of the subcatchment areas and is listed in **Table 11-2**. These numbers correspond to the percentage of precipitation that becomes surface runoff.

COMBINED SEWER OVERFLOWS

As discussed above, during significant storm events CSOs within the Bowery Bay WWTP service area discharge to the East River and Flushing Bay.

The 2008 FGEIS estimated that the CSO outfalls, which may potentially be affected by development within the District and on Lots B and D, discharged 5,711.68 million gallons per year to area waterways. The 2008 FGEIS concluded that generally, the impact of CSO events on local water quality is short-term at most locations, due principally to the mixing caused by tidal currents of the receiving waters and the fact that sanitary flows are diluted by runoff.

Table 11-2
Existing Surface Coverage

Portion of Project Site	Surface Type	Surface Areas (sf)	Percent Coverage	Discharge Method	Weighted Runoff Coefficient
Special Willets Point District	Building Roofs	822,456	31%	Separate Sewer	
	Paved Surfaces	1,773,138	67%	Separate Sewer	
	Grass/Softscape	41,071	2%	Separate Sewer/Infiltration	
	Total	2,636,665	100%		0.89
Willets West	Paved Surfaces	1,318,507	90%	Separate Sewer	
	Grass/Softscape	152,697	10%	Separate Sewer/Infiltration	
	Total	1,471,204	100%		0.78
South Lot and Lot D	Paved Surfaces	486,784	100%	Separate Sewer	
	Total	486,784	100%		0.85
Lot B	Building Roofs	1,207	1%	Separate Sewer	
	Paved Surfaces	179,539	93%	Separate Sewer	
	Grass/Softscape	12,543	6%	Separate Sewer/Infiltration	
	Total	193,289	100%		0.81
Sources: Langan.					

In September 2010, New York City released its NYC Green Infrastructure Plan which outlines strategies to achieve better water quality and sustainability benefits than a traditional “all-grey” strategy. Goals of the plan relate to reductions in CSO volume, the capture of rainfall from impervious surfaces, and the provision of quantifiable sustainability benefits. The plan has five key components: 1) build cost-effective grey infrastructure, 2) optimize the existing wastewater system, 3) control runoff from 10 percent of impervious surfaces through green infrastructure, 4) institutionalize adaptive management, model impacts, measure CSOs, and monitor water quality, and 5) engage and enlist stakeholders. An update to the plan was released in 2011.

Flushing Bay and Flushing Creek are identified in the plan as individual watersheds where CSO reductions will have the greatest impact. The plan identifies opportunities within each watershed.

Since the project site does not have a combined sewer system, it is not included in the boundaries of either the Flushing Bay or Flushing Creek identified as an “opportunity” in either drainage area.

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

In the future without the proposed project in 2018, 2028, and 2032, it is assumed that no changes will occur on any portion of the project site with regard to development of new buildings or uses. Therefore, it is expected that the District will continue to contain its existing industrial and auto-related uses, and that the Willets West, South Lot, Lot D, and Lot B portions of the project site will continue to serve the parking needs of CitiField. These uses will be able to connect to and make use of the municipal infrastructure improvements currently under construction.

WATER SUPPLY

With no changes on the project site, it is expected that existing water demand will remain unchanged in the future without the proposed project; therefore, future water demand is estimated at 159,964 gpd for 2018, 2028, and 2032.

It is expected that the improvements undertaken by EDC (i.e., the replacement of a 12-inch water main along 126th Street between Northern Boulevard to a point between 35th and 36th Avenues) will be complete by 2018.

SANITARY SEWAGE

With no changes on the project site, it is expected that existing sanitary sewage generated will remain unchanged in the future without the proposed project; therefore, future sanitary sewage generation is estimated at 62,767 gpd for 2018, 2028, and 2032. This flow will likely continue to be directed to the existing septic system. A limited volume may be directed to the new infrastructure currently under construction, once completed.

It is expected that the improvements undertaken by EDC (i.e., the new 36-inch gravity sanitary sewer running west from 126th Street and the 16-inch and 24-inch segments on 126th Street) will be complete by 2018.

STORMWATER

It is expected that the improvements undertaken by EDC (i.e., the 7.5-by-5-foot outfall in 126th Street, the 7.5-by-5-foot storm sewer in 126th Street, and the 60-inch stub sewer connection in 34th Avenue) will be complete by 2018. As it is assumed that land use would remain the same, no changes to the runoff coefficient would occur in 2018, 2028, or 2032.

COMBINED SEWER OVERFLOWS

DEP is working to reduce CSOs in specific areas through construction projects that include upgrades at WWTP, storm sewer expansions, and CSO retention tanks. DEP also has a citywide effort to better manage stormwater using green infrastructure, consistent with its *NYC Green Infrastructure Plan*, updated in 2011. These green infrastructure measures include source controls, or the detention or retention of stormwater runoff through capture and controlled release, infiltration into the ground, vegetative uptake, and evapotranspiration. DEP will continue to implement a range of measures to control CSOs.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

PHASE 1A (2018)

The first phase of the project (Phase 1A) would consist of the remediation and development of an approximately 23-acre portion of the Special Willets Point District and the development of “Willets West” on the existing parking lot west of CitiField. Development within the District would consist of a hotel with approximately 200 rooms and approximately 30,000 square feet of retail space along the east side of 126th Street, a 20-foot-wide public esplanade, and an approximately 2,800-space surface parking area that would also be used for active recreation for a portion of the year.

Willets West—an entertainment and retail center of approximately 1.4 million gross square feet (approximately one million sf of gross leasable area)—would be developed on a portion of the surface parking lot west of CitiField. The complex would include retail stores, movie theaters, restaurant and food hall spaces, and entertainment venues. Surface parking and a parking structure also would be developed in this location, including 2,500 new spaces for the entertainment/retail center and 400 spaces of replacement parking for use by the Mets.

In addition, the westernmost CitiField surface parking lot south of Roosevelt Avenue (a portion of the South Lot) would be redeveloped as a structured parking facility, to replace a portion of the CitiField parking spaces formerly located on the Willets West portion of the project site.

The project site is within the Federal Emergency Management Agency (FEMA) 100-year floodplain.¹ FEMA and New York City Building Code flood resistant design requirements must therefore be taken into account within the design, while complying with the Special Willets Point District zoning elevation requirements. During Phase 1A, the majority of the project site is anticipated to remain at the existing grade, with the hotel and commercial space finished floor elevations being elevated to comply with the design flood elevation. It is anticipated that the remainder of the extent of Phase 1A would be raised above the floodplain elevation or otherwise designed to comply with FEMA and New York City Building Code requirements prior to completion of the development of Phase 1B in 2028.²

WATER SUPPLY

Proposed Improvements

Special Willets Point District

Water service within the District would be supplied from a new water main network, to be constructed by the developer. Existing DEP water mains in the developed area (35th Avenue south to Willets Point Boulevard, 126th Street east to 127th Street) would be demolished or abandoned as required. New 12-inch ductile iron pipe (DIP) water mains would be constructed in 35th Avenue, 126th Street, 127th Street, and Willets Point Boulevard. The buildings to be constructed in Phase 1A would tie directly into these new water mains.

An easement would be established over the new 12-inch DIP water main and the existing 72-inch PRCP water main in Willets Point Boulevard in the portion of the street that would be demapped prior to Phase 1A construction.

Willets West

A new on-site water service loop is proposed to connect to the existing 12-inch water main within Roosevelt Avenue at the southwest corner of the Willets West portion of the project site and to the existing 8-inch water main that serves CitiField. Some existing segments of CitiField's water supply system would be demolished as they would no longer be needed once the new water service loop is constructed. This new water service would serve the proposed Willets West development while maintaining CitiField's water network.

South Lot and Lot D

Service to the parking structure proposed for the South Lot would be provided by a lateral connection to the 12-inch water main within Roosevelt Avenue.

¹ On February 25, 2013, FEMA released Advisory Base Flood Elevation (ABFE) maps for areas in New York City, including the project site. More recently, FEMA released preliminary work map data for the area, replacing the ABFE information as the best available flood hazard data. Although the preliminary work maps are subject to further review, when they are ~~Although the ABFE is subject to further review, if it is adopted~~ as part of a future updated Flood Insurance Rate Map, the proposed project would comply with these flood elevations as required by the New York City Building Code.

² As discussed in Chapter 16, "Greenhouse Gas Emissions and Climate Change," prior to the placement of fill, the project sponsor would submit to the Mayor's Office of Environmental Coordination an assessment of the appropriate grade for the District in light of all available information concerning potential sea level rise due to climate change.

Willets Point Development

Lot B

No development is projected for Lot B by 2018, and thus no new water service would be required.

Water Demand

In the 2018 analysis year, the project site is projected to result in a demand for 661,500 gpd of water (see **Table 11-3**), which is an increase of 501,536 gpd over the No Action condition.

Table 11-3
2018 Projected Water Demand

Proposed Use	Size	Demand Type	Rate	Phase 1A Consumption (gallons per day)
Retail	1,430,000 sf	Domestic	0.24 gpd/sf	343,200
		Air Conditioning	0.17 gpd/sf	243,100
Hotel ¹	200 (rooms)	Domestic	120 gpd/occupant	48,000
	160,000 sf	Air Conditioning	0.17 gpd/sf	27,200
Total	1,590,000		NA	661,500
Increase from the Future Without the Proposed Project				501,536
Note: 1. Assumes 2 occupants per room.				
Source: Rates from 2012 <i>CEQR Technical Manual</i> .				

The 2008 FGEIS projected a demand for water of 4.36 million gallons per day (mgd) for the full development of the District and concluded that the infrastructure was sufficient to meet that demand. The Phase 1A water demand would be substantially lower than 4.36 mgd. Therefore, based on the FGEIS conclusion, the infrastructure is sufficient to supply the Phase 1A projected water demand.

SANITARY SEWAGE

Proposed Improvements

As part of the development of Phase 1A, QDG would develop and submit a DEP-approved ADP reflecting Phase 1A street demapping.

Special Willets Point District

Sanitary sewage from the District would be directed to the 36-inch PRCP sanitary sewer currently being constructed by EDC across CitiField's northern and western parking lots. This sewer will provide two stubbed connections in 126th Street: one 24-inch and one 16-inch. The 16-inch connection would be partially extended south along 126th Street by QDG, in accordance with the ADP to be developed for the proposed project. Buildings developed within the District as part of Phase 1A would discharge to this new sewer extension.

Willets West

Sanitary sewage from the development of Willets West would be directed to the 36-inch gravity sewer currently being constructed across CitiField's northern and western parking lots. Based on current estimates, the 36-inch sewer currently under construction has adequate capacity to support the sanitary flow from the Willets West development.

South Lot and Lot D

No sanitary sewage connection would be provided for South Lot and Lot D, as these areas would be developed as parking facilities.

Lot B

No development is projected for Lot B by 2018. Therefore, no sanitary sewage connection would be provided for Lot B.

Sanitary Sewage Calculation

In the 2018 analysis year, the project site would result in 391,200 gpd of sanitary sewage, an increase of 328,433 gpd over the No Action condition.

Based on current estimates and the previous EDC studies, the 37th Avenue pump station, the 36-inch sewer currently under construction, and the 24-inch sewer downstream from it, would have sufficient capacity to accommodate the development proposed under Phase 1A. QDG would work with DEP to assess the operations of the existing pump station. Based on this assessment, QDG would replace or upgrade components identified as requiring such work as a result of the additional flows associated with the Phase 1A development.

The 2008 FGEIS projected an increase of sanitary flow to the Bowery Bay WWTP of approximately 2.8 mgd for the full development of the District; the Phase 1A sanitary sewage generation would be substantially lower than this number. The 2008 FGEIS concluded that the WWTP would have sufficient capacity to accommodate a flow increase of 2.8 mgd. Therefore, it is expected that the Bowery Bay WWTP would have adequate capacity to accommodate the Phase 1A development.

*STORMWATER**Proposed Improvements*

As part of the development of Phase 1A, QDG would develop and submit a DEP-approved ADP that would reflect the Phase 1A street demapping.

Special Willets Point District

As described above, the development within the District in Phase 1A would be predominately surface parking and hardscape, with retail uses and a 200-bed hotel along 126th Street.

As discussed above, the stormwater outfall at 126th Street is being improved by EDC, and a 7.5-by-5-foot box storm sewer is currently under construction in 126th Street by EDC. This new sewer will discharge to Flushing Bay and will extend south to a point between 34th and 35th Avenues. During construction of Phase 1A, the box storm sewer would be partially extended south along 126th Street by QDG. The extension would comply with the ADP to be developed and filed by QDG. Per the draft ADP, stormwater runoff tributary to the new box storm sewer would be restricted to a surface runoff coefficient of 0.85. Stormwater runoff discharging to the box storm sewer in 126th Street would be treated to comply with NYSDEC regulations. A NYSDEC SPDES GP-010-001 permit would be obtained, which requires the implementation of a SWPPP.

Willets West

As described above, the Willets West development would include a retail/entertainment space with parking garages, surface parking, hardscaping, and landscaping.

Stormwater runoff from the Willets West development would continue to drain to the on-site 72-inch NYSDOT storm sewer that discharges to Flushing Bay. To meet NYSDOT requirements, existing stormwater runoff amounts tributary to the 72-inch sewer would be maintained. The design will be coordinated with the NYSDOT during the design phase.

Willets Point Development

South Lot and Lot D

Stormwater management for the area would maintain existing conditions by discharging runoff to the existing NYSDOT/DPR sewer network in the western portion of the site. Drainage to this network will need to be treated to comply with NYSDEC regulations. Detention requirements will be verified with DEP during the design phase.

Lot B

No development is projected for Lot B by 2018. Therefore, stormwater runoff from Lot B would continue to be detained, treated, and directed to the 54-inch DEP storm sewer in 126th Street before being discharged into Flushing Bay via the 60-inch outfall on 126th currently under construction.

Stormwater Calculation

Table 11-4 presents the stormwater calculations for the Phase 1A development.

Table 11-4
2018 Proposed Surface Coverage

Portion of Project Site	Surface Type	Surface Areas (sf)	Percent Coverage	Discharge Method	Weighted Runoff Coefficient	Existing Weighted Runoff Coefficient	Incremental Change in Runoff Coefficient
Special Willets Point District	Building Roofs	600,294	23%	Separate Sewer			
	Paved Surfaces	2,011,957	76%	Separate Sewer			
	Grass/Softscape	24,414	1%	Separate Sewer/Infiltration			
	Total	2,636,665	100%		0.88	0.89	-0.01

	Total	193,289	100%		0.81	0.81	No Change
Notes: ¹ No change in use or surface coverage between existing and 2018 No Action conditions.							
Sources: Langan.							

COMBINED SEWER OVERFLOWS

Using the existing site plan and the proposed site plan for each site, the DEP Flow Volume Calculation Matrix was completed for the existing and With Action conditions. The calculations from the Flow Volume Calculation Matrix help to determine the change in wastewater volumes to the combined sewer system from existing conditions to the future with the proposed project. Runoff volumes were calculated for four rainfall volume scenarios with varying durations. The summary tables, taken from the DEP Flow Volume Calculation Matrix, are included in **Table 11-5**.

Table 11-5
DEP Flow Volume Calculation Matrix:
2018 Existing and With Action Volume Comparison

Rainfall Volume (in.)	Rainfall Duration (hr.)	Runoff Volume Direct Drainage (MG)	Runoff Volume To CSS (MG)	Sanitary Volume To CSS (MG)	Total Volume To CSS (MG)	Runoff Volume To River (MG)	Runoff Volume To CSS (MG)	Sanitary Volume To CSS (MG)	Total Volume To CSS (MG)

2.50	19.50	0.24	0.00	0.00	0.00	0.24	0.00	0.00	0.00
Notes:									
¹ In the existing condition, sanitary flow from the District is conveyed to septic systems and is not conveyed to the combined sewer system.									
² No change in use or surface coverage between existing and 2018 No Action conditions.									
CSS=combined sewer system; MG=million gallons									

The calculations from the flow volume calculation matrix determine the wastewater volumes to the downstream sewer system from the existing and With Action conditions. Runoff volumes are calculated for four rainfall volume scenarios with varying durations; all stormwater runoff would continue to be directly discharged to Flushing Bay. The increases in sanitary sewer discharge from the project site for the above rainfall volume-duration scenarios from the Phase 1A flows, in comparison to the existing condition range from:

- Special Willets Point District: 0.01 to 0.04 MGD
- Willets West: 0.05 to 0.27 MGD
- South Lot and Lot D: No change
- Lot B: No change

Phase 1A would be consistent with the City's goal to reduce CSO events by requiring construction and maintenance of a separate storm and sanitary sewer system. The 2008 FGEIS found that there would be no significant increase in frequency or volume of CSO events as a result of the Willets Point Development Plan, since CSOs primarily relate to stormwater inputs, which greatly exceed sanitary flow rates during storm events. As a result of this conclusion, it is

Willets Point Development

anticipated that the sanitary flow from the proposed project in 2018, which is less than the sanitary flow projected in the 2008 FGEIS, would not significantly affect the number of annual CSO events. In addition, water conservation measures and low-flow fixtures as required by New York City Plumbing Code (Local Law 33 of 2007) would be employed to minimize sanitary sewage flow to the existing combined sewer system. Stormwater runoff from the project site in 2018 would be treated in accordance with the project SWPPP, and conveyed to Flushing Bay through a separate storm sewer system in accordance with an ADP to be developed by QDG and approved by DEP.

PHASE 1B (2028)

In Phase 1B, the interim surface parking lot/recreational space created during Phase 1A within the Special Willets Point District would be developed with: approximately 2.49 million sf of residential use (2,490 units), 875,000 sf of retail, 500,000 sf of office use, approximately 235,000 sf of hotel use (290 rooms), 25,000 sf of community facility use, and a 105,000 sf public school, along with parking and more than five acres of new public open space. In addition, new structured parking facilities would be constructed on South Lot and Lot D to replace the CitiField parking spaces formerly located within the District. The 75 accessory parking spaces created in Phase 1A for the hotel would remain in the District.

Construction of the new Van Wyck Expressway access ramps—which was anticipated in the 2008 FGEIS and for which the City has received approval from the Federal Highway Administration—is slated to be completed in 2024.

As discussed previously, the project site is within the FEMA 100-year floodplain. FEMA and New York City Building Code flood resistant design requirements along with the Special Willets Point District zoning elevation requirements would need to be taken into consideration for the Phase 1B development. It is anticipated that prior to the completion of the Phase 1B development, site grades within the Phase 1A/Phase 1B portion of the District would be raised to levels at or above the floodplain elevation. This change in grade may be achieved through the placement of fill and/or construction of structured platforms. Grade transitions between the new streets constructed in Phase 1B and the existing street grades that would remain in the Phase 2 area would be required until Phase 2 development is completed in 2032.

WATER SUPPLY

Proposed Improvements

For Phase 1B, water service for Willets West and the District would remain as constructed in Phase 1A. For South Lot and Lot D, the proposed parking structures would be directly connected to the 12-inch DEP water main in Roosevelt Avenue. No new development is projected for Lot B by 2028, and thus no new water service would be required. Consultation with DEP prior to Phase 1B development would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required.

Water Demand

In the 2028 analysis year, the proposed development is projected to result in a demand for 1,763,360 gpd of water (see **Table 11-6**), which, when combined with demand from Phase 1A of the project, would be an increase of 2,264,896 gpd over the No Action condition.

Table 11-6
2028 Projected Water Demand

Proposed Use	Size	Demand Type	Rate	Phase 1B Consumption (gpd)	Overall (Phase 1A and 1B) (gpd)
Residential	7,022 people ¹	Domestic	100 gpd/person	702,200	702,200
	2,490,000 sf	Air Conditioning	0.17 gpd/sf	423,300	423,300
Commercial/Office	525,000 sf	Domestic	0.10 gpd/sf	52,500	52,500
		Air Conditioning	0.17 gpd/sf	89,250	89,250
Retail	875,000 sf	Domestic	0.24 gpd/sf	210,000	553,200
		Air Conditioning	0.17 gpd/sf	148,750	391,850
Hotel ²	290 rooms	Domestic	120 gpd/occupant	69,600	117,600
	235,000 sf	Air Conditioning	0.17 gpd/sf	39,950	67,150
School	996 (seats)	Domestic	10 gpd/seat	9,960	9,960
	105,000 sf	Air Conditioning	0.17 gpd/sf	17,850	17,850
Total	4,230,000 sf		NA	1,763,360	2,424,860
Increase from the Future Without the Proposed Project				1,603,396	2,264,896
Notes: 1. The number of residents was calculated based on 2,490 units constructed in Phase 1B, which is based on the average household size of 2.82 residents per unit in Queens. 2. Assumes 2 occupants per room. Source: Rates from 2012 <i>CEQR Technical Manual</i> .					

It is anticipated that the water supply system would have adequate capacity to accommodate the Phase 1B.

SANITARY SEWAGE

Proposed Improvements

As part of the development of Phase 1B, QDG would develop and submit a DEP-approved ADP reflecting the Phase 1B street demapping.

For the District, an on-site sanitary sewer network would be constructed, as needed, by QDG to serve the Phase 1B development. This network would be located along the alignment of proposed private streets and would discharge to the off-site 16-inch DEP sanitary sewer in 126th Street.

For the Willets West portion of the project site, the sanitary sewage system would remain as constructed in Phase 1A.

No sanitary sewage connection would be provided for South Lot and Lot D, as these areas would be developed as parking facilities.

No development is projected for Lot B by 2028. Therefore, no sanitary sewage connection would be provided for Lot B.

Sanitary Sewage Generation

In the 2028 analysis year, the project site is projected to result in a sanitary sewage generation of 1,044,260 gpd which, when combined with demand from Phase 1A of the project, would result in 1,435,460 gpd and an increase of 1,372,693 gpd over the 2028 No Action condition.

It is expected that the 36-inch sewer currently under construction would have adequate capacity to accommodate the Phase 1B development. However, upgrades to the 24-inch sewer under the Grand Central Parkway, the 37th Avenue pump station and its associated downstream force main would likely be required. If needed to support Phase 1B development, QDG would fund

Willets Point Development

the 37th Avenue pump station upgrade, at the time when the need arises. It is anticipated that the upgrade would occur within the existing city land or rights-of-way. These upgrades would be in conformance with the DEP-approved ADP.

The 2008 FGEIS projected an increase of sanitary flow to the Bowery Bay WWTP of approximately 2.8 mgd for the full development of the District; the Phase 1B sanitary sewage generation would be substantially lower than this number. The 2008 FGEIS concluded that the WWTP would have sufficient capacity to accommodate a flow increase of 2.8 mgd. Therefore, it is expected that the Bowery Bay WWTP would have adequate capacity to accommodate the Phase 1B development.

STORMWATER

Proposed Improvements

As noted above, as part of development of Phase 1B, QDG would develop and submit a DEP-approved ADP reflecting the Phase 1B street demapping. Any existing DEP stormwater sewers in newly demapped roads would be abandoned by the City and turned over to the property owner, or would require the establishment of easements to allow for DEP access and maintenance. Stormwater detention and BMPs installed in Phase 1A will be supplemented or replaced as required to accommodate Phase 1B development.

Stormwater runoff discharging to Flushing Bay will be treated to comply with NYSDEC regulations. A SPDES permit would be obtained and a SWPPP would be implemented.

Phase 1B development within the District would primarily consist of retail/residential buildings with hardscape, landscape, and open spaces scattered throughout. Stormwater runoff would discharge to the 7.5-by-5-foot box storm sewer constructed by the EDC. Alternatively, the developer may seek to construct new storm sewers, per the ADP to be developed. Stormwater detention and BMPs would be installed to meet DEP and NYSDEC regulations. The design team would explore options for reuse of stormwater, including the possibility of collection and treatment of stormwater for on-site irrigation.

No new development would occur in the Willets West area in Phase 1B. Therefore, for the Willets West area, the stormwater management system would remain as constructed in Phase 1A.

For South Lot and Lot D, the Phase 1B development would include the construction of two new parking garages along with additional surface parking. Stormwater management implemented in Phase 1A would be maintained. Stormwater runoff from new development would be discharged to the existing NYSDOT and DPR storm sewer network. Runoff would be detained to maintain existing flow rates to the existing sewer system. Alternatively, QDG may seek to construct new storm sewers in Roosevelt Avenue and 126th Street in accordance with the ADP to be developed.

No development is projected for Lot B by 2028. Therefore, stormwater runoff from Lot B would continue to be detained, treated, and directed to the 54-inch DEP storm sewer in 126th Street before being discharged into Flushing Bay via the new storm outfall, currently under construction by the EDC.

Stormwater Calculation

Based on the proposed Phase 1B site plan, the proposed surface coverages and weighted runoff coefficients for each site is included in **Table 11-7**. For the roof courtyard area it is assumed that the area will be comprised of 50 percent pervious surfaces (due to plants/grass in the courtyard) and 50 percent impervious surfaces resulting in a weighted runoff coefficient of 0.76 for the roof courtyard.

Table 11-7
2028 Proposed Surface Coverage

Site	Surface Type	Surface Areas (sf)	Percent Coverage	Discharge Method	Weighted Runoff Coefficient	Existing Weighted Runoff Coefficient	Incremental Change in Runoff Coefficient
Special Willets Point District	Building Roofs	949,654	36%	Separate Sewer			
	Paved Surfaces	1,370,366	52%	Separate Sewer

¹ In the existing condition, sanitary flow from the District is conveyed to septic systems and is not conveyed to the combined sewer system.									
² No change in use or surface coverage between existing and 2028 No Action conditions.									

Willets Point Development

The calculations from the flow volume matrix determine the wastewater volumes to the downstream sewer system from the existing and With Action (Phase 1A and 1B) conditions. Runoff volumes are calculated for four rainfall volume scenarios with varying durations; all stormwater runoff would continue to be directly discharged to Flushing Bay. The increase in sanitary sewer discharge from the project site for the above rainfall volume-duration scenarios from the Phase 1A and 1B flows, in comparison to the existing condition range from:

- Special Willets Point District: 0.17 to 0.89 MGD
- Willets West: 0.05 to 0.27 MGD
- South Lot and Lot D: No change
- Lot B: No change

Like Phase 1A, Phase 1B would be consistent with the City's goal to reduce CSO events by requiring construction and maintenance of a separate storm and sanitary sewer system. The 2008 FGEIS found that there would be no increase in frequency of CSO events as a result of the Willets Point Development Plan, since CSOs primarily relate to stormwater inputs, which greatly exceed sanitary flow rates during storm events. As a result of this conclusion, it is anticipated that the sanitary flow from the proposed project in 2028, which would be less than projected in the 2008 FGEIS, would not affect the number of annual CSO events. In addition, water conservation measures and low-flow fixtures as required by New York City Plumbing Code (Local Law 33 of 2007) would be employed to minimize sanitary sewage flow to the existing combined sewer system. Stormwater runoff from the project site in 2028 would be treated in accordance with the project SWPPP, and conveyed to Flushing Bay through a separate storm sewer system in accordance with an ADP to be developed by QDG and approved by DEP.

PHASE 2 (2032)

By 2032, the Phase 2 of the proposed project would result in a total development of 2.65 million sf of retail use, 5.85 million sf of residential development (5,850 units; 16,497 total residents), 230,000 sf of school space; approximately 500,000 gsf of office; up to 400,000 gsf of convention center use; up to 560,000 gsf of hotel use (approximately 700 rooms); up to 150,000 gsf of community facility use; approximately 230,000 gsf of public school use; and a minimum of 8 acres of publicly-accessible open space. In addition, by 2032 Lot B is projected to be developed with 184,500 sf of retail use and 280,000 sf of office use.

As discussed previously, the project site is within the FEMA 100-year floodplain. FEMA and New York City Building Code flood resistant design requirements along with the special district zoning elevation requirements would need to be taken into consideration for the Phase 2 development. It is anticipated that prior to completion of the Phase 2 development, the site grades within the Phase 2 portion of the District would be raised to levels at or above the floodplain elevation. This change in grade may be achieved through the placement of fill and/or construction of structured platforms.

WATER SUPPLY

Proposed Improvements

For the District, consultation with DEP would be required to determine water supply requirements for Phase 2 of the proposed project. Additional internal water services would likely be required to support the proposed development in 2032.

Consultation with DEP would be required to determine if upgrades (including a new regulator and connection) to the 72-inch water main in Willets Point Boulevard would be required to support Phase 2 development, if not already constructed in a prior phase. Replacement of the water main may also be triggered by any substantive grade change over the main.

All existing streets in the District would be demapped before the construction of Phase 2. Any existing DEP water mains located within newly demapped streets would either be abandoned by the City and turned over to the property owner or would require the establishment of easements to allow for DEP access and maintenance.

No new development would occur in the Willets West area in Phase 2. For Willets West, water service would remain as constructed in Phase 1A.

No new development would occur on the South Lot or Lot D in Phase 2. Therefore, for this portion of the project site, water service would remain as constructed in Phase 1B.

For Lot B, no new water infrastructure would be required.

Water Demand

In the 2032 analysis year, the project would result in a demand for 2,066,285 gpd of water (see **Table 11-9**), which, when combined with demand from Phases 1A and 1B of the project, would be an increase of 4,331,181 gpd over the No Action condition.

Table 11-9
2032 Projected Water Demand

Proposed Use	Size		Rate	Phase 2 Consumption (gpd)	Overall (Phase 1A, 1B and 2) (gpd)
Residential	9,475 (people) ¹	Domestic	100 gpd/person	947,500	1,649,700
	3,360,000 sf	Air Conditioning	0.17 gpd/sf	571,200	994,500
Commercial/Office	405,000 sf	Domestic	0.10 gpd/sf	40,500	93,000
		Air Conditioning	0.17 gpd/sf	68,850	158,100
Retail	529,500 sf	Domestic	0.24 gpd/sf	127,080	680,280
		Air Conditioning	0.17 gpd/sf	90,015	481,865
Hotel ²	210 (rooms)	Domestic	120 gpd/occupant	50,400	168,000
	165,000 sf	Air Conditioning	0.17 gpd/sf	28,050	95,200
School	1,344 (seats)	Domestic	10 gpd/seat	13,440	23,400
	125,000 sf	Air Conditioning	0.17 gpd/sf	21,250	39,100
Convention Center ³	400,000 sf	Domestic	0.10 gpd/sf	40,000	40,000
		Air Conditioning	0.17 gpd/sf	68,000	68,000
Total	4,984,500 sf		NA	2,066,285	4,491,145
Total Compared to No Action				1,906,321	4,331,181
Notes: 1. The number of residents was calculated based on 3,360 units constructed in Phase 2, which is based on the average household size of 2.82 residents per unit in Queens. 2. Assumes 2 occupants per room. 3. No rate provided in <i>CEQR Technical Manual</i> for Convention Center therefore Commercial/Office rate was used. Source: Rates from 2012 <i>CEQR Technical Manual</i> .					

As stated above, the 2008 FGEIS projected a demand for water of 4.36 mgd. The water demand for the proposed project in 2032, at 4.49 mgd, would be a 3.0 percent increase over the projected FGEIS water demand; therefore, it is anticipated that the water supply system would have adequate capacity to accommodate the full build-out of the project site.

SANITARY SEWAGE

Proposed Improvements

For the District, new sanitary-sewer trunk mains are anticipated in Northern Boulevard, , 126th Street, Willets Point Boulevard, and Roosevelt Avenue consistent with the DEP-approved ADP. The current draft ADP shows the largest sewer to be 24-inch diameter DIP. An ADP specific to the proposed project would have to be developed and filed by the designated developer of Phase 2 and would need to reflect the latest street demapping. The entirety of the streets in the District would be demapped before Phase 2 construction; this demapping will be reflected in a revised ADP to be developed by QDG.

Sanitary flow would be collected locally and directed to the sewer-main network before eventually discharging to the 36-inch gravity-sewer connection at the intersection of 126th Street and the former 34th Avenue. This 36-inch sewer was sized to accept sanitary sewage from the full development of the District, as analyzed in the 2008 FGEIS.

No new development is proposed for the Willets West area in 2032. Therefore, for Willets West, sanitary sewerage would remain as constructed in Phase 1A.

No new development is proposed for the South Lot and Lot D in 2032. As per Phase 1B development, no sanitary sewerage would be provided for the South Lot and Lot D in Phase 2 because these sites would be developed as parking facilities.

For Lot B, a sanitary sewage connection would be made to the surrounding CitiField or Willets West on-site sanitary infrastructure.

Sanitary Sewage Generation

In 2032, the proposed development would generate 1,218,920 gpd of sanitary sewage, which, when combined with demand from Phases 1A and 1B, would result in 2,654,380 gpd and an increase of 2,591,613 gpd over the 2032 No Action condition.

Per the draft ADP, upgrades to the 37th Avenue pump station and its force main would be required for Phase 2. Specifically, the operating capacity of the 37th Avenue pump station (currently 3,450 gpm) would need to be upgraded to 8,400 gpm. If not upgraded to support Phase 1B, upgrades to the 24-inch sewer under the Grand Central Parkway, the 37th Avenue pump station and its associated downstream force main would be required and would be funded by the developer of Phase 2. These upgrades would be in conformance with the DEP approved ADP.

The 2008 FGEIS projected an increase of sanitary flow to the Bowery Bay WWTP of approximately 2.8 mgd; the sanitary sewage generation of the proposed project in 2032 would be lower than this number. The approximate sanitary sewage generated is slightly lower due to changes in CEQR methodology. The 2001 *CEQR Technical Manual* specified a rate of 112 gpd/person for residential uses; however, this rate was reduced to 100 gpd/person in the 2010 *CEQR Technical Manual*, which was the basis for Technical Memorandum #4 flow estimates, as well as the 2012 *CEQR Technical Manual*, which is the basis for flow calculations presented here.

STORMWATER

Proposed Improvements

For the District, the Phase 2 development would consist of a retail/residential community with hotels, offices, open spaces, and a convention center. Per the draft ADP, DEP storm sewers would be required in 126th and 127th Streets, with ancillary sewers required in Northern Boulevard, 34th Avenue, Willets Point Boulevard, and Roosevelt Avenue. Storm sewers would be reinforced concrete to meet DEP standards. An ADP specific to the proposed project would have to be developed and filed by the designated developer of Phase 2 and would need to reflect the latest street demapping.

Stormwater runoff would be collected locally, treated using NYSDEC-approved methods, and directed to the stormwater outfalls in Flushing Bay. The draft ADP addresses the need for two outfalls: one in 126th Street currently being constructed by the EDC and one in 127th Street. A 60-inch outfall would be required in 127th Street for Phase 2.

Similar to the 2008 FGEIS, stormwater detention and BMPs would be required and installed to meet DEP and NYSDEC regulations within the District. Stormwater management within the District would be implemented through the use of selected BMPs which could include:

- On-site detention facilities (roof detention, underground storage tanks or tanks within the buildings);
- Increased quantity, density, and diversity of trees;
- Sustainable irrigation and landscaping practices;
- Graywater recycling for individual building sites;
- Integration of vegetated swales;
- Green roofs;
- Inline pipe storage;
- Decorative wet ponds;
- Detention dry ponds;
- Proprietary pre-treatment structures (e.g., Stormceptor, Vortechinics);
- Bioengineered and structural practices to reduce and control runoff;
- Stormwater recycling facilities (reuse for toilet flushing, custodial work, landscape irrigation, and other uses to reduce demand for potable water);
- Optimized right-of-way drainage;
- Vegetated filters and buffer strips;
- Water quality inlets including oil and grit separators, media filters, and high-volume treatment proprietary devices;
- Surface, perimeter, and/or underground sand filters;
- Infiltration trenches, with under-drain and overflow to a control structure connection to a storm sewer;
- Bioretention-shallow swales, with under-drain and overflow to a control structure connection to a storm sewer; and
- Other low-impact, effective measures.

Willets Point Development

The entirety of the streets in the District would be demapped before the construction of Phase 2; this demapping would be reflected in a revised ADP to be developed. Any existing DEP storm sewers present in newly demapped streets would be abandoned by the City and turned over to the property owner or would require the establishment of easements to allow for DEP access and maintenance. A SPDES permit would be obtained for any discharge to the Flushing Bay outfalls and a project SWPPP would be implemented.

No new development is proposed for the Willets West area in 2032. Therefore, for Willets West, the stormwater management system would remain as implemented in Phase 1A.

No new development is proposed for the South Lot or Lot D in 2032. Therefore, for South Lot and Lot D, the stormwater management system would remain as implemented in Phase 1B.

It is anticipated that stormwater runoff from Lot B would continue to be detained, treated, and directed to the 54-inch DEP storm sewer in 126th Street before being discharged into Flushing Bay via the 60-inch outfall on 126th, currently under construction.

Stormwater Calculation

Based on the proposed Phase 2 site plan, the proposed surface coverages and weighted runoff coefficients for each site is included in **Table 11-10**. For the roof courtyard area it is assumed that the area will be comprised of 50 percent pervious surfaces (due to plants/grass in the courtyard) and 50 percent impervious surfaces resulting in a weighted runoff coefficient of 0.76 for the roof courtyard.

Table 11-10
2032 Proposed Surface Coverage

Site	Surface Type	Surface Areas (sf)	Percent Coverage	Discharge Method	Weighted Runoff Coefficient	Existing Weighted Runoff Coefficient	Incremental Change in Runoff Coefficient
Special Willets Point District	Building Roofs	1,233,909	47%	Separate Sewer

Notes: ¹ In the existing condition, sanitary flow from the District is conveyed to septic systems and is not conveyed to the combined sewer system. CSS=combined sewer system; MG=million gallons									

The calculations from the flow volume matrix determine the wastewater volumes to the downstream sewer system from the existing and With Action (Phase 1A, 1B and 2) conditions. Runoff volumes are calculated for four rainfall volume scenarios with varying durations; all stormwater runoff would continue to be directly discharged to Flushing Bay. The increase in sanitary sewer discharge from the project site for the above rainfall volume-duration scenarios from the overall cumulative flows, in comparison to the existing condition range from:

- Special Willets Point District: 0.36 to 1.82 MGD
- Willets West: 0.05 to 0.27 MGD
- South Lot and Lot D: No change
- Lot B: 0.01 to 0.06 MGD

Phase 2 of the proposed project would be consistent with the City's goal to reduce CSO events by requiring construction and maintenance of a separate storm and sanitary sewer system. The 2008 FGEIS found that there would be no significant increase in frequency or volume of CSO events as a result of the Willets Point Development Plan, since CSOs primarily relate to stormwater inputs, which greatly exceed sanitary flow rates during storm events. As a result of this conclusion, it is anticipated that the sanitary flow from the RWCDs, which would be less than projected in the 2008 FGEIS, would not significantly affect the number of annual CSO events. In addition, water conservation measures and low-flow fixtures as required by New York

Willeys Point Development

City Plumbing Code (Local Law 33 of 2007) would be employed to minimize sanitary sewage flow to the existing combined sewer system. Stormwater runoff from the project site during all phases of the RWCDS would be treated in accordance with the project SWPPP, and conveyed to Flushing Bay through a separate storm sewer system in accordance with an ADP that would be developed by QDG and approved by DEP. *

A. INTRODUCTION

This chapter describes existing and future New York City solid waste disposal practices, and assesses the impacts of the reasonable worst-case development scenario's (RWCDS) solid waste generation on the City's collection needs and disposal capacity in comparison to the conclusions of the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda. The proposed project's consistency with the City's Solid Waste Management Plan is also assessed.

PRINCIPAL CONCLUSIONS

This analysis finds that the RWCDS would not result in significant adverse impacts to solid waste and sanitation that were not addressed in the 2008 FGEIS or subsequent technical memoranda.

While the RWCDS would create new demands on solid waste and sanitation services, the municipal systems serving the project site area have adequate capacity to meet the projected increases in demand. The New York City Department of Sanitation (DSNY), which collects solid waste and recyclables, is anticipated to provide municipal solid waste and sanitation services to the District. Private carters currently and will continue to provide these services to non-residential users. The RWCDS would cumulatively increase the volumes of solid waste and recyclables, but would not affect the delivery of these services, nor place a significant burden on the City's solid waste management services (public or private) or require any amendments to the City's solid waste management objectives as stated in the SWMP. As disclosed in the 2008 FGEIS, the RWCDS would displace waste transfer businesses from the District by 2032, but this displacement would not have a significant adverse impact on the waste and sanitation services in Queens or in New York City.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS concluded that, although the Willets Point Development Plan and anticipated development on Lots B and D would cumulatively increase the volumes of solid waste and recyclables, but would not affect the delivery of these services, nor place a significant burden on the City's solid waste management services (public or private). The 2008 FGEIS noted that the Willets Point Development Plan would displace two waste transfer businesses from the District, but that this displacement would not have a significant adverse impact on waste and sanitation services in Queens or in New York City. Therefore, the 2008 FGEIS concluded that no significant adverse impacts on solid waste and sanitation services would result from the Willets Point Development Plan and the anticipated development on Lots B and D. Subsequent technical memoranda approved on September 23, 2008, November 13, 2008, November 18, 2009, and

February 10, 2011 also concluded that proposed revisions to the Willets Point Development Plan would not have significant adverse impacts on solid waste and sanitation services.

C. METHODOLOGY

According to the 2012 *CEQR Technical Manual*, a solid waste and sanitation services assessment should be conducted if a project would generate solid waste or enacts regulatory changes affecting the management of the City's waste, or if the action involves the construction, operation, or closing of any type of solid waste management facility. The manual also states that projects with a generation rate of less than 100,000 pounds per week are not considered large and do not warrant detailed analysis.

To assess the potential impacts on solid waste and sanitation services from the RWCDs, this chapter:

- Describes the existing solid waste management services in the project site area, and using solid waste generation rates for typical land uses and activities provided in the 2012 *CEQR Technical Manual*, assesses current levels of solid waste generation for all portions of the project site (Willets West, the Special Willets Point District, and the Roosevelt Avenue parking areas) as well as Lot B;
- Assesses the effect of the potential displacement of one existing waste transfer business in the District;
- Determines future solid waste demands with the RWCDs; and
- Assesses the effects of this incremental demand on municipal and private sanitation services.

D. EXISTING CONDITIONS

SANITATION SERVICES

In the City of New York, residential and institutional refuse is handled by DSNY, while solid waste from commercial and manufacturing uses is collected by private carters.

Commercial carters pick up solid waste from businesses, manufacturers, and offices and take the waste materials to transfer stations where the recyclable materials are separated from the solid waste. The solid waste is consolidated into larger trucks for transport and disposal in landfills outside of New York City. The recyclable materials are sold and transported to manufacturing facilities. Private carters handle about 14,830 tons per week of recyclables and solid waste. In addition, private carters handle about 19,070 tons per day (tpd) of construction debris and excavated materials.¹ DSNY collects approximately 16,500 tpd of refuse and recyclables, of which approximately 5,000 tons are recycled.

The City's solid waste management services are undertaken in accordance with the existing Solid Waste Management Plan (SWMP) (September 2006), which is the responsibility of DSNY. The existing SWMP, which modified the City's previously approved 1992 plan (as amended in 1996 and 2000), was approved for submission to the New York State Department of Environmental Conservation (NYSDEC) by a resolution of the City Council on July 19, 2006.

¹ The DSNY SWMP anticipates and provides for a projected increase in solid waste generation citywide over the 20-year plan period as a result of population growth and non-specific development. By 2020, the SWMP anticipates a daily increase of 2,145 tons, or 12.7 percent.

The City adopted the existing plan on July 27, 2006. The SWMP was approved by NYSDEC in a letter received by DSNY on October 27, 2006.

The SWMP establishes a hierarchy of preferred solid waste management methods to reduce and process solid waste generated within the City. The objectives of the SWMP are, in order of importance: waste minimization; reuse, recycling, or composting; and export for out-of-city disposal. The SWMP mandates that solid waste be transferred to solid waste management facilities located in each borough, including special (hazardous materials) waste collection sites, composting facilities, and bulk residential waste sites. Local Law 19 of 1989 requires that DSNY and private carters collect recyclable materials and deliver them to material recovery facilities. New York City residents are required to separate aluminum foil, glass, plastic, and metal containers, and newspapers and other paper wastes from household waste for separate collection. Under the law, commercial establishments are also subject to recycling requirements. Businesses must source-separate certain types of paper wastes, cardboard, metal items, and construction wastes. Food and beverage establishments must recycle metal, glass, and plastic containers, and aluminum foil, in addition to meeting the commercial recycling requirements.

The new SWMP includes a Long Term Export Program for residential waste. The City's Long Term Export Program is anticipated to be implemented through: the development of four converted marine transfer stations; the award of up to five contracts with private transfer stations for barge or rail export of DSNY-managed waste for disposal; and an intergovernmental agreement to dispose of a portion of Manhattan's DSNY-managed waste at a Port Authority waste-to-energy facility in New Jersey. The new SWMP includes the use of up to nine converted marine transfer station (MTS) facilities and private transfer stations within the five boroughs at which solid waste will be consolidated, containerized, and barged or railed out of the City. The barges used at MTS facilities would transport sealed intermodal containers capable of being transported on barge or rail. The four converted MTS facilities would be designed to each process at least 4,290 tpd and accommodate 30 collection vehicles per hour. In the interim, pending implementation of each Long Term Export Program element, DSNY-managed municipal solid waste would be trucked out of the City.¹

The new SWMP also proposes three broad categories of action to address traffic issues associated with commercial waste handling as follows: improve conditions at and around transfer stations; facilitate a transition from a network heavily reliant on trucks to one that relies primarily on barge and rail; and redistribute private transfer capacity from a small number of communities that have the largest proportion of the system's impacts.

SOLID WASTE GENERATION

The District portion of the project site currently has a number of active uses that generate solid waste. Waste generated by the single existing occupied dwelling unit in the District is assumed to be negligible. The solid waste generated by the portions of the project site currently used for parking—Willets West, South Lot, and Lot D—as well as Lot B, which is also currently used for parking, is assumed to be minimal and therefore has not been included in the calculations provided below.

Table 14-1 of the *CEQR Technical Manual* provides solid waste generation rates for various categories of land use. These rates were utilized in this analysis. Table 14-1 provides generation

¹ DSNY, *Comprehensive Solid Waste Management Plan*, September 2006.

Willets Point Development

rates for two categories of industrial uses. The average of the two rates, estimated at 183 pounds per week per employee, is utilized in this analysis as representative of construction, manufacturing, and auto uses (not including auto wholesale and auto retail). The waste generated by waste management and remediation businesses was assumed to be the waste generated by employees and was approximated with the office use solid waste generation rate of 13 pounds per week per employee.

Based on these assumptions, the project site's current uses generate a total of approximately 165,310 pounds (about 12 tpd) of solid waste per week (see **Table 12-1**). These private business uses are served by commercial solid waste and recycling management companies.

Table 12-1
Existing Solid Waste Generation in the Project Site

Existing Use	Number of Businesses	Number of Employees	Solid Waste Rate lbs/wk/employee	Total lbs/week
Auto Businesses (not including wholesale and retail)	158	469	183 ¹	85,827
Construction	6	147	183 ¹	26,901
Manufacturing	5	72	183 ¹	13,176
Wholesale Trade (including auto wholesale)	11	265	66	17,490
Retail Trade (including auto retail)	31	210	79	16,590
Administrative & Support, Waste Management and Remediation ²	5	178	13	2,314
Accommodation and Food	4	12	251	3,012
Total				165,310
Notes: ¹ Assumed to be the average of two industrial use generation rates in the 2012 <i>CEQR Technical Manual</i> . ² Assumed that the only waste generated by the waste management businesses was that of employees, approximated with the office use generation rate from the <i>CEQR Technical Manual</i> . ³ Based on the general retail use waste generation rate from the <i>CEQR Technical Manual</i> .				

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

As described in Chapter 1, "Project Description," for the purposes of a conservative analysis, the RWCDS for this EIS assumes that no changes to land use occur on the project site by 2032. Thus, no changes with respect to solid waste generation from the project site are expected to occur by 2032. As described in Chapter 2, "Land Use, Zoning, and Public Policy," a number of development projects are anticipated to be constructed in the surrounding area by 2032. There would also be some changes in the City's waste management services. The existing North Shore MTS, which serves the project site, has been demolished, and a new MTS is under construction on the same site in College Point. The new MTS is expected to be completed in the near future, by June 2013. The new MTS will receive and allow for containerization of solid waste. Containerized solid waste will then be exported from the new MTS by barge. The new MTS will have the capacity to handle up to 3,672 tpd of solid waste under normal conditions. Under upset conditions as a result of an event that reduces processing capacity of one or more elements of DSNY's waste management system—such as fire or equipment outages—thereby requiring a temporary reallocation of municipal solid waste from other wastesheds to this transfer station for a period of a few days duration, allowable capacity of the new MTS will be 4,290 tpd of solid waste. In the event of a public emergency event affecting the entire or large part of DSNY's waste management system, thereby requiring DSNY—acting on the basis of protecting the public health—to use the maximum design capacity of the North Shore MTS, 5,280 tpd of solid

waste will be allowed. However, the average daily throughput is expected to be 2,200 tons of DSNY waste and 1,000 tons of commercial waste.¹

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

RWCDS

Consistent with the conclusions of the 2008 FGEIS and subsequent technical memoranda, the RWCDS is anticipated to result in the displacement of two waste transfer businesses currently operating in the District (Tully Environmental and Crown Container). It is anticipated that the businesses would be able to continue operations through Phases 1A and 1B, but would be displaced upon completion of Phase 2 of the proposed project. Crown Container is authorized to process construction and demolition debris. The permitted capacity of Crown Container is small, and the waste generated at that facility could be absorbed at other facilities in Queens or other boroughs. Tully Environmental currently processes putrescible municipal (DSNY) waste under a contract with the City, and is permitted to handle up to 1,375 tpd.² The North Shore MTS, when completed, will have the capacity to process the municipal waste currently handled by Tully. Until it is displaced by Phase 2, Tully could still maintain handling of waste generated by the private sector, per its permitted capacity.

The proposed project would place additional demands on the solid waste and sanitation services in the area. To determine future solid waste volumes, solid waste generation rates from the 2012 *CEQR Technical Manual* and from published environmental impact statements were applied to the RWCDS. **Table 12-2** presents the cumulative solid waste volumes expected under the RWCDS using these assumptions. As shown in the table, it is estimated that the RWCDS would generate approximately 924,486 pounds of solid waste per week (66 tpd) in 2032.³ This daily demand would result in a 54 tpd increase in 2032 over the existing demand and is the equivalent of 0.4 percent of the total amount of solid waste currently handled each day in New York City. This is not a significant increase in the City's solid waste stream.

While most of the existing solid waste generated by the project site is from non-residential uses and is therefore collected by private carting companies, in 2032 an estimated 251,589 pounds (18 tpd) per week of solid waste generated by the proposed project would be from residential, school, and community facility uses. This residential and public solid waste would be collected by DSNY. According to the 2012 *CEQR Technical Manual* guidelines, the typical DSNY collection truck has a capacity of 12.5 tons. Therefore, the proposed project would be expected to generate solid waste for DSNY collection that would require up to two added truckloads per day in 2032. This is not a significant impact on solid waste services for DSNY.

¹ North Shore Marine Transfer Station Waste Containerization Facility Part 360 Permit Application, January 2007.

² <http://www.tullyconstruction.com/company/affiliates/> (October 2012).

³ The solid waste generated by the portions of the project site currently used for parking—Willets West, South Lot, and Lot D—as well as Lot B, which is also currently used for parking, is assumed to be minimal and therefore has not been included in the calculations in Table 12-2.

Table 12-2
Solid Waste Generation of the RWCDS in 2032

Use	Size (gsf)	Individuals	Solid Waste Rates (lbs/week)	Total (lbs/week)
Residential	5,850,000 (5,850 units)	16,029 residents ¹	41 per resident	239,850
Retail	2,834,500	7,086 employees	79 per employee	559,814
Office	780,000	3,120 employees	13 per employee	40,560
Convention Center	400,000	160 employees	13 per employee ²	2,080
Hotel	560,000 (625 rooms)	259 employees	75 per employee	19,444
Community Facility	150,000	150 employees	13 per employee ³	1,950
School	230,000 (2,340 seats)	2,340 pupils 213 employees	3 per pupil 13 per employee	9,789
Total				873,487
Lot B Retail	184,500	461 employees	79 per employee	36,439
Lot B Commercial	280,000	1,120 employees	13 per employee	14,560
RWCDS⁴				924,486
Notes: ¹ Based on the average household size of 2.74 for Community District 7 in 2010 Census data. ² Based on solid waste generation rate used in the <i>Atlantic Yards Arena and Redevelopment Project FEIS</i> . ³ Based on the solid waste generation rate used in the <i>West Harlem Rezoning and Academic Mixed-Use Development FEIS</i> . ⁴ As discussed in Chapter 1, "Project Description," the RWCDS includes the potential future development on Lot B as analyzed in the 2008 FGEIS, as well as the proposed project.				

The non-residential solid waste (retail, office, convention center, and hotel uses) would be collected by private contractors. The total amount of this waste would be 672,897 pounds (48 tpd) per week in 2032. Given that the typical collection truck averages a 12.5-ton capacity, the RWCDS would require up to four private contractor truckloads per day. This is not a significant increase in demand and would be met by private-sector response to the increase in service needs.

In summary, this analysis finds that the RWCDS would not result in any significant adverse impacts related to solid waste and sanitation that were not addressed in the 2008 FGEIS and subsequent technical memoranda. Additionally, the proposed project would not conflict with or require any amendments to the City's solid waste management objectives as stated in the SWMP. *

A. INTRODUCTION

This chapter discusses the energy demand and energy efficiency measures anticipated with the reasonable worst-case development scenario (RWCDS), and assesses whether the RWCDS would result in any significant adverse impacts on energy transmission and generation that were not addressed in the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda.

PRINCIPAL CONCLUSIONS

Consistent with the findings of the 2008 FGEIS and subsequent technical memoranda, this analysis concludes that the proposed project would not result in significant adverse impacts on energy demand and infrastructure. The cumulative annual energy consumption that would result from the RWCDS, including the potential future development on Lot B, would be 1,952,503 million British thermal units (BTUs). Phase 1A and 1B are subject to Local Law 86 of 2005 (see New York City Charter section 224.1) and the project sponsor would comply with the requirements thereof. To the extent Local Law 86 of 2005 applies to any portion of Phase 2, the City would further ensure that the sponsor for Phase 2 complies with the requirements thereof. Accordingly, in Phase 1A, the retail buildings, including the proposed development on the Willets West site, will be designed and constructed to achieve Leadership in Energy and Environmental Design (LEED) silver certification for core and shell (LEED-CS), and the hotel building will be designed and constructed to achieve LEED silver certification for new construction (LEED-NC). In Phases 1B and 2, as set forth in the FGEIS and reiterated in Technical Memorandum #4, all portions of the project within the Willets Point Special District will be required to achieve LEED for neighborhood development (LEED-ND) certification. Phase 1B buildings will also comply with all the applicable requirements of Local Law 86 of 2005. Specifically, retail, hotel, community facility and office buildings will be designed and constructed to achieve LEED silver certification pursuant to the LEED rating system that is most appropriate under Local Law 86 (see Section 10-02 of chapter 10 of title 43 of the Rules of the City of New York). To meet the requirements of LEED and the energy cost reduction requirements of Local Law 86 of 2005 that are applicable to the project under NYC Charter section 224.1(b)(2)(ii), energy efficiency measures would be incorporated into building designs, as described in this chapter. The requirements of Local Law 86 of 2005 and the commitments set forth in this chapter would be incorporated into the development agreements and/or amended lease agreements. The provisions of the development agreements and/or amended lease agreements, relating to substance and enforceability of these commitments, would be subject to approval by Mayor's Office of Environmental Coordination.

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The annual energy consumption projected in the 2008 FGEIS for the development proposed within the Special Willels Point District and the anticipated potential future development on Lots B and D was 1,176,686 million BTUs. To account for the 2010 revisions of the *City Environmental Quality Review (CEQR) Technical Manual*, Technical Memorandum #4 (TM4) projected the annual energy consumption for these same uses, with the updated energy consumption rates. With the updated rates, the annual energy consumption was projected to be 1,576,095 million BTUs. Although a number of energy efficiency and sustainability measures to reduce energy consumption were proposed in the 2008 FGEIS, the beneficial effect of these measures was not quantified.

C. METHODOLOGY

As discussed below, this chapter:

- Presents data on the existing energy distribution system and estimated energy usage for existing conditions;
- Determines future energy demands with the RWCDS for each development phase, using energy consumption rates for typical land uses provided in the 2012 *CEQR Technical Manual* and the 2001 *CEQR Technical Manual* energy consumption rate for parking (for which a consumption rate is not available in the 2012 *CEQR Technical Manual*).
- Assesses the effect of this incremental energy demand on the local distribution system and regional energy supplies; and
- Describes features that may be incorporated into the project design for the purposes of minimizing project demands on energy infrastructure and services.

D. EXISTING CONDITIONS

ENERGY SUPPLY AND TRANSMISSION

Within New York City, electricity is generated and delivered to most users by Consolidated Edison (Con Edison) as well as a number of independent power companies. Electrical energy in New York City is drawn from a variety of sources that originate both within and outside the City. These include non-renewable sources, such as oil, natural gas, and coal fuel; and renewable sources, such as hydroelectricity and, to a much lesser extent, biomass fuels, solar power, and wind power. Electricity consumed in New York City is generated in various locations, including sites within New York City, locations across the Northeast, and places as far away as Canada.

Con Edison distributes power throughout the City and Westchester County. Transmission substations receive electricity from the regional high voltage transmission system and reduce the voltage to a level that can be delivered to area substations. Area substations further reduce the voltage to a level that can be delivered to the distribution system, or the street “grid.” Within the grid, voltage is further reduced for delivery to customers.

In 2011, approximately 58 billion kilowatt hours (KWH), or 198 trillion BTUs were delivered in Con Edison’s service area. In addition, Con Edison supplied approximately 129 trillion BTUs of natural gas and approximately 22 billion pounds of steam, which is equivalent to approximately

26 trillion BTUs.¹ Overall, approximately 353 trillion BTUs of energy are consumed within Con Edison's New York City and Westchester County service area annually.

According to the Con Edison *2011 Annual Report*, the peak electrical demand for New York City in summer 2010 was 13,189 megawatts (MW). Typically, electricity generated within the City is sufficient to satisfy demand. However, during the summer peak demand period, this electricity is often supplemented by the Northeast transmission grid. As a result, there is an ongoing service and distribution improvement program for infrastructure that upgrades high demand zones.

ENERGY INITIATIVES

The New York State Energy Planning Board was created by a 2009 law that calls on the Board to complete a new State Energy Plan on or before March 15, 2013. The State Energy Plan will focus on reliably meeting projected future energy demands, while balancing economic development, climate change, environmental quality, health, safety and welfare, transportation, and consumer energy cost objectives. New York State also has goals to reduce electricity consumption by 15 percent and to provide 30 percent of the electricity used in the state from renewable resources by 2015.

In New York City, one of the nation's first green building laws was adopted in 2005 (Local Law 86). Local Law 86 of 2005 requires new buildings, additions, and substantial building reconstruction work in capital projects that receive city funds to be built in accordance with the rigorous standards of the LEED® green building rating systems developed by the U.S. Green Building Council (USGBC). It also requires that most of this work, as well as larger lighting, boiler, HVAC controls, and plumbing upgrade work, be designed to reduce the use of both energy and potable water well beyond that required by the current NYC building code.

Additionally, in New York City, the Greener, Greater Building Plan program was implemented through local legislation to target energy efficiency in large existing buildings. The program consists of four local laws that require that large buildings annually benchmark their energy performance (Local Law 84 of 2009); that a local energy code be adopted (Local Law 85 of 2009); that every 10 years these buildings conduct an energy audit and retro-commissioning (Local Law 87 of 2009); and that by 2025, the lighting in non-residential spaces be upgraded to meet code and large commercial tenants be provided with sub-meters (Local Law 88 of 2009). Together, these initiatives would help improve energy efficiency and reduce energy consumption.

EXISTING DEMAND

To estimate the existing annual energy consumption for the project site, the following rates (in 1,000 BTU per square foot), provided in Table 15-1 of the *2012 CEQR Technical Manual*, were used:

- **Commercial** (Office, Retail, and Other, including miscellaneous auto uses, a residence, a deli, and a private club): 216.3; and
- **Industrial** (storage, recycling uses, non-retail auto uses, transportation, consumption, distribution and manufacturing): 554.3.

¹ Consolidated Edison Annual Report, 2011.

Willets Point Development

As no consumption rate is listed for parking garages in the 2012 *CEQR Technical Manual*, a rate of 27,400 BTU per square foot was used based on 2001 *CEQR Technical Manual* Table 3N-1.

Based on these rates, current annual energy use for the project site is estimated to be approximately 211,633 million BTUs, as shown in **Table 13-1**.

Table 13-1
Existing Annual Energy Consumption
for the Project Site

Existing Use	Square Feet (sf)	Million BTU
Office	69,293	14,988
Industrial	228,214	126,499
Retail	46,230	10,000
Parking Garage	262,019	7,179
Other	244,879	52,967
Total		211,633

E. THE FUTURE WITHOUT THE PROPOSED PROJECT

Without the proposed project, it is conservatively assumed that the uses currently within the project site would remain, although it is possible that within the District, some properties that are currently vacant would be reused and that some limited development could occur. Therefore, in the future without the proposed project, it is assumed that the project site's energy demand would be consistent with existing conditions. The peak summer demand is projected to grow at an annual rate of 0.84 percent until 2021. While projections beyond 2021 are not available at this time, it is likely that the rate of demand growth would continue to increase, as population grows. To some extent, the demand growth would be slowed down by increases in energy efficiency. It is expected that measures will be taken to provide adequate electrical capacity to the New York City metropolitan area through 2032 and beyond. It is also assumed that Con Edison would continue to implement its electrical distribution improvement programs in Queens. In the future, it is expected that the existing trend toward sustainability would lead to greater energy efficiency in the City.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT

To provide the energy service needed for the RWCDs to the project site, upgrades to electrical and gas transmission lines and additional facilities serving the area would be needed. Within the Special Willets Point District and adjoining streets, gas mains, service lines, and metering would need to be reconstructed as part of the proposed project. Improvements to the local distribution grid would also be required, and coordination with Con Edison is under way to determine the nature and timing of the needed improvements. The District's zoning regulations allow for the provision of a new cogeneration facility and/or substation within that portion of the project site, provided they would primarily serve the District. Such facilities are not currently proposed as part of Phases 1A and 1B but may be included as part of Phase 2. Any such facilities, if proposed or needed at a future time, would require further study and additional approvals. Such

studies would require information on the facility location, size, and design that is not presently available. If proposed as part of Phase 2, these uses would be subject to separate environmental and public review processes.

As described in the 2008 FGEIS, the Willets Point Development Plan had been accepted as a pilot LEED-ND project by USGBC. Phase 1A and 1B are subject to Local Law 86 of 2005 (see New York City Charter section 224.1) and the project sponsor would comply with the requirements thereof. To the extent Local Law 86 of 2005 applies to any portion of Phase 2, the City would further ensure that the sponsor for Phase 2 complies with the requirements thereof. Accordingly, in Phase 1A, the retail buildings, including the proposed development on the Willets West site, will be designed and constructed to achieve LEED silver certification for core and shell (LEED-CS), and the hotel building will be designed and constructed to achieve LEED silver certification for new construction (LEED-NC). In Phases 1B and 2, as set forth in the FGEIS and reiterated in Technical Memorandum #4, all portions of the project within the Willets Point Special District will be required to achieve LEED for Neighborhood Development (LEED-ND) certification. Phase 1B buildings will also comply with all the applicable requirements of Local Law 86 of 2005. Specifically, retail, hotel, community facility and office buildings will be designed and constructed to achieve LEED silver certification pursuant to the LEED rating system that is most appropriate under Local Law 86 (see Section 10-02 of chapter 10 of title 43 of the Rules of the City of New York). The requirements of Local Law 86 of 2005 and the commitments set forth in this chapter would be incorporated into the development agreements and/or amended lease agreements. The provisions of the development agreements and/or amended lease agreements, relating to substance and enforceability of these commitments, would be subject to approval by the Mayor's Office of Environmental Coordination. To meet the requirements of LEED and the energy cost reduction requirements of Local Law 86 of 2005 a number of features that would lead to energy savings would be considered. The following measures would likely be included or considered, on a building-by-building basis: building orientation to minimize energy use; energy efficient building envelope to reduce heating and cooling demand; high efficiency heating, ventilation and air conditioning (HVAC) systems; highly reflecting roofing materials that would reduce air conditioning needs in the summer and help mitigate the urban heat island effect¹; window glazing to optimize daylighting, heat loss and solar heat gain; motion sensors and lighting and climate controls; efficient lighting and elevators, and appliances; efficient, directed exterior lighting; and third party building commissioning to ensure energy performance.

In addition, the proposed school in the District would be built according to the New York City School Construction Authority's *New York City Green Schools Guide*, as revised in May 2009. The *Green Schools Guide* addresses the sustainable design, construction, and operation of new schools, modernizing projects, and school renovations in New York City.

The specific energy-saving and sustainable design measures that would be implemented as part of the development that would occur in Phase 2, or on Lot B, would be defined at the time when the developer for those areas is selected. It is expected that the measures would be similar to

¹ The urban heat island effect refers to the temperature difference between urban areas and surrounding suburban or rural areas. Much of this temperature difference is attributed to the prevalence of dark roofs and dark colored pavement, which absorb more heat than lighter surfaces, as well as the declining presence of vegetation in cities.

Willeys Point Development

those described above for Phases 1A and 1B. Any future development on Lot B, which is under lease to the Queens Baseball Company (QBC), would require an amendment to the current lease agreement and discretionary approval by the New York City Industrial Development Agency (IDA), acting through the New York City Department of Parks and Recreation (DPR), which administers the IDA lease. This action would be the subject of a separate environmental review process subject to CEQR. Based on the anticipated size of the potential future development on Lot B, it is likely that a determination of consistency with PlaNYC would be required in this separate environmental review process. The demonstration of consistency with PlaNYC would require implementation of sustainable design measures that are likely to be similar to those for the proposed project.

Although the proposed project would implement the sustainable design measures discussed above, for the purposes of a conservative analysis the resulting energy savings were not accounted for in the calculation of energy demand.

ENERGY DEMAND WITH THE PROPOSED PROJECT

The annual energy consumption was projected for each project phase, use type, and location (i.e. Special Willeys Point District, Willeys West, and South Lot/Lot D), as well as for Lot B. The following energy consumption rates (in 1,000 BTU per square foot) from 2012 *CEQR Technical Manual* Table 15-1 were used:

- **Commercial** (Retail, Hotel, Community Facility, Office, Convention Center): 216.3;
- **Institutional** (School): 250.7; and
- **Large Residential** (Residential): 126.7.

For parking uses, as described under “Existing Conditions,” a factor of 27,400 BTU per square foot was used (based on 2001 *CEQR Technical Manual* Table 3N-1). It was assumed that the proposed parking facilities would average 340 sf per parking spot, consistent with the assumption made in the 2008 FGEIS.

As shown in **Table 13-2**, the proposed project’s energy demand in 2032 would be approximately 1,846,461 million BTUs. The energy demand of the RWCDS in 2032 (including the potential development of Lot B) would be approximately 1,952,503 million BTUs. Coordination with the utilities is underway to ensure that the needed infrastructure to supply the projected demand would be in place to serve the development in each project phase.

The improvements in local connections that are necessary to provide energy services to the proposed project would not adversely impact the local system. Therefore, the RWCDS would not have any significant adverse impacts on energy systems. In addition, as described above, the proposed project would include a number of energy conservation measures, which would decrease the overall energy demand presented above.

In summary, this analysis finds that the RWCDS would not result in any significant adverse impacts related to energy that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

Table 13-2
Annual Energy Consumption for RWCDs, by Phase

Use	Project Area	Phase 1A (2018)	Phase 1B (2028)	Phase 2 (2032)	Totals by Use
Retail	SWPD	6,489	189,263	74,624	270,375
	WW	302,820	0	0	302,820
Hotel	SWPD	34,608	50,831	35,690	121,128
Residential	SWPD	0	315,483	425,712	741,195

Convention Center	SWPD	0	0	86,520	86,520
Proposed Project Total	All	382,979	745,298	718,184	1,846,461
Retail	Lot B	0	0	39,907	39,907
Office	Lot B	0	0	60,564	60,564
Parking	Lot B	0	0	5,571	5,571
RWCDS Total¹	All	382,979	745,298	824,226	1,952,503
Notes: All figures above shown in million BTUs. Until completion of Phase 2, some of the existing uses within the District may remain. The energy use for existing businesses during Phase 1A/1B would be lower than the total energy for existing uses shown in Table 13-1 . SWPD = Special Willets Point District WW = Willets West ¹ The RWCDs includes the potential future development on Lot B as analyzed in the 2008 FGEIS.					

*

A. INTRODUCTION

This chapter assesses whether any changed background conditions or the differences between the reasonable worst-case development scenario (RWCDS) and the program assessed in the 2008 Final Generic Environmental Impact Statement (FGEIS) and subsequent technical memoranda would result in any significant adverse impacts on transportation that were not addressed in the 2008 FGEIS and subsequent technical memoranda.

The project site includes the surface parking lots immediately west and south of CitiField and south of Roosevelt Avenue, and the Special Willets Point District (the District) located across 126th Street from CitiField and generally bounded by 126th Street to the west, Roosevelt Avenue to the south, the Van Wyck Expressway and an undeveloped parcel owned by the Metropolitan Transportation Authority (MTA) to the east, and Northern Boulevard to the north. Willets Point is also within close proximity to primary highways including the Whitestone Expressway to the north and east, the Grand Central Parkway to the west, and the Long Island Expressway (LIE) to the south. This network of highway mainlines and ramp interchanges carries significant traffic volumes and frequently experiences congestion during peak travel periods. Sections of the local street network adjacent to the District, such as Roosevelt Avenue and Northern Boulevard, experience moderate to heavy traffic volumes during peak travel periods, while other sections, such as 126th Street, have substantial amounts of unused capacity during typical weekday and weekend conditions.

The project site lies between the neighborhoods of Corona/North Corona to the west and Downtown Flushing—a key commercial center and intermodal transportation hub—across the Flushing River to the east. Both Northern Boulevard and Roosevelt Avenue provide connections between the project site, Downtown Flushing, and Corona. In addition, the close proximity of the project site to CitiField results in significant changes to traffic characteristics and operations on roadways in the area before and after Mets home games. With parking lot entrances located along Roosevelt Avenue, 126th Street, and Stadium Road, access and egress to CitiField during pre- and post-game periods significantly affects traffic conditions on both the highway and local street networks near Willets Point.

The proposed project, with its mix of uses, would replace the existing approximately 4,100-space surface parking lot adjacent to the west side of CitiField and lower-density uses currently within the District and, thus, would generate significantly more traffic on the adjacent local street and highway network. This would be developed over the course of three continuous phases: Phase 1A; Phase 1B; and Phase 2. In addition, the demapping and subsequent reconstruction of streets within the District would create new access and egress points along Northern Boulevard and 126th Street and alter traffic circulation patterns on the adjacent street network. Improvements to connections between the Van Wyck Expressway and the District, which would be built between Phases 1A and 1B, would further modify travel patterns in the study area.

This chapter addresses the potential traffic, parking, transit, and pedestrian impacts of the proposed project for each phase of development. The approach routes to the study area traverse intersections along Northern Boulevard, Astoria Boulevard, Roosevelt Avenue, Sanford Avenue, Main Street, College Point Boulevard, 126th Street, and 34th Avenue, as well as exits from the Grand Central Parkway and the Van Wyck/Whitestone Expressway, both north and west of Willets West and the District. Transit facilities include the Met-Willets Point subway station and area bus routes and primary pedestrian corridors are situated along 126th Street and Roosevelt Avenue. In accordance with the approach outlined in Chapter 1, “Project Description,” this chapter analyzes the impact of trips generated by all three phases of the proposed project.

PRINCIPAL CONCLUSIONS

TRAFFIC AND PARKING

As was found in the FGEIS, the proposed project is expected to be a significant traffic generator on both the highways surrounding the project site—including the Grand Central Parkway, the Van Wyck Expressway, and the Whitestone Expressway—and the local street network over the course of its three buildout phases. The With Action volume increments generated by the proposed project would be as follows:

Phase 1A of the project is expected to generate 883 vehicles per hour (vph) in the AM peak hour, 2,517 vph in the midday peak hour, 2,618 vph in the PM peak hour on a typical weekday without a Mets home game, and 3,132 vph in the Saturday midday peak hour on a non-game weekend. For peak hours with a Mets home game, the proposed project is expected to generate 2,324 vph in the weekday PM (evening) pre-game peak hour, 2,313 vph in the Saturday afternoon pre-game peak hour, and 2,063 vph in the Saturday evening post-game peak hour.

With the completion of Phase 1B, 2,649 vehicles per hour (vph) would be generated in the AM peak hour, 5,152 vph in the midday peak hour, 5,420 vph in the PM peak hour on a typical weekday without a Mets home game, and 5,855 vph in the Saturday midday peak hour on a non-game weekend. For peak hours with a Mets home game, the proposed project is expected to generate 4,194 vph in the weekday PM (evening) pre-game peak hour, 4,576 vph in the Saturday afternoon pre-game peak hour, and 4,037 vph in the Saturday evening post-game peak hour.

With full buildout at the completion of Phase 2, including the potential future development of Lot B, 4,533 vehicles per hour (vph) would be generated in the AM peak hour, 7,551 vph in the midday peak hour, 8,361 vph in the PM peak hour on a typical weekday without a Mets home game, and 8,740 vph in the Saturday midday peak hour on a non-game weekend. For peak hours with a Mets home game, the proposed project is expected to generate 6,339 vph in the weekday PM (evening) pre-game peak hour, 6,981 vph in the Saturday afternoon pre-game peak hour, and 6,445 vph in the Saturday evening post-game peak hour. This includes volume increment generated by the proposed project and the Lot B development.

Future baseline (future No Action) volumes, to which the traffic generated by the proposed project and Lot B would be added, and future levels of service are expected to be significantly worse than existing conditions due to background traffic growth plus traffic generated from additional background development projects. Traffic generated by the proposed project would be in addition to high baseline volumes and poor levels of service at many of the analysis intersections and along key sections of the highway network.

As a result, by Phase 1A, the proposed project is expected to have significant traffic impacts at 15 of the ~~29~~ 32 intersections analyzed¹, both signalized and unsignalized, for the future With Action condition in the weekday AM peak hour, ~~17~~ 16 of ~~29~~ 32 in the weekday midday peak hour, and 20 of ~~29~~ 32 in the weekday PM and Saturday midday non-game peak hour. On game days, ~~21~~ 23 of ~~29~~ 32 intersections analyzed would have significant traffic impacts during the PM pre-game weekday peak hour, ~~17~~ 19 of ~~29~~ 32 intersections analyzed would have significant traffic impacts during the Saturday pre-game peak hour and ~~19~~ 21 of ~~29~~ 32 intersections analyzed would have significant impacts during the Saturday post-game peak hour.

In Phase 1B, the proposed project is expected to have significant traffic impacts at 19 of the ~~30~~ 33 intersections analyzed in the weekday AM peak hour, ~~20~~ 21 of ~~30~~ 33 in the weekday midday peak hour, ~~22~~ 21 of ~~30~~ 33 in the weekday PM peak hour, and ~~25~~ 24 of ~~30~~ 33 in the non-game-Saturday midday peak hour. On game days, 22 of ~~30~~ 33 intersections analyzed would have significant traffic impacts during the PM pre-game weekday peak hour, ~~20~~ 21 of ~~30~~ 33 intersections analyzed would have significant traffic impacts during the Saturday pre-game peak hour and ~~21~~ 23 of ~~30~~ 33 intersections analyzed would have significant impacts during the Saturday post-game peak hour.

By full buildout in Phase 2, including the potential future development of Lot B, the proposed project is expected to have significant traffic impacts at ~~22~~ 23 of the ~~31~~ 34 intersections analyzed in the weekday AM peak hour, ~~and 26~~ 28 of ~~31~~ 34 in the weekday midday peak hour, ~~29 of 34 in the weekday PM peak hour~~, and ~~27 of 34 in the~~ Saturday midday non-game peak hours. During the PM pre-game weekday peak hour, ~~25~~ 28 of ~~31~~ 34 intersections analyzed would have significant traffic impacts, and during the Saturday pre-game and post-game peak hours, ~~23~~ 25 of ~~31~~ 34 intersections analyzed would have significant impacts. Potential measures to mitigate these projected significant adverse impacts are described in Chapter 21, “Mitigation.”

Although the proposed project’s analyses include new access ramps to and from the Van Wyck Expressway at the northeastern corner of the District that would be completed around 2024 in advance of Phase 1B of the proposed project, it is projected that in each proposed buildout phase (both before and after the construction of the ramps) some sections of the highway mainlines and critical ramp junctions would incur level of service degradations and be significantly impacted. By Phase 1A, ~~three~~ five of the seven highway mainline locations analyzed (including the westbound Grand Central Parkway and the southbound Whitestone Expressway) and five of the 12 ramp locations would be significantly impacted during at least one of the seven peak analysis hours. The new access ramps are expected to reduce the use by project-generated traffic of certain local streets to access the project site; however, project generated traffic would also cause significant traffic increases and level of service degradations on the highway network in Phases 1B and 2 with the proposed ramps in place. By Phase 1B, five of the seven highway mainline locations analyzed (including both directions of the Grand Central Parkway and Whitestone and Van Wyck Expressways) and seven of the 12 ramp locations would be significantly impacted during at least one peak hour. By Phase 2, ~~five~~ four of the ~~six~~ seven highway mainline locations analyzed (including the westbound Grand Central Parkway, and both directions of the Whitestone and Van Wyck Expressways) and ~~eight~~ seven of the 12 ramp locations would be significantly impacted during at least one peak hour.

¹ Three study area intersections were added for the analysis between completion of the Draft SEIS and completion of this Final SEIS.

Willets Point Development

By its full buildout in Phase 2, the proposed project would provide sufficient new off-street and on-street parking as part of the development to service its peak demand of 5,850 spaces. The redevelopment of the District would include the demapping and realignment of the local street network within the boundaries of the District, which is expected to increase the available on-street parking supply. The proposed project's expected parking needs would be provided within the immediate area by full buildout, and it is not expected that project-generated traffic would have to seek parking opportunities outside of the area. In all phases, Willets West's proposed 2,500 accessory parking spaces would be sufficient to meet parking demands generated by the development at Willets West. Under Phase 1A, all project-generated parking demand within the District would be satisfied by accessory parking provided as part of the proposed project. Under Phase 1B, the 2,700 accessory parking spaces that would accompany development in the District would fully satisfy project demand in 2028 except from 2 to 4 PM on Saturday where there would be a shortfall of up to approximately 45 spaces. However, this demand is expected to be fully satisfied by available on-street spaces within the District and off-street spaces in facilities within walking distance of the District.

In addition to providing accessory parking for project demand, the proposed project would also replace the 4,100 Mets parking spaces in the main CitiField lots to the west of the stadium that would be displaced by the Willets West development. These replacement spaces would be distributed amongst an interim parking facility in the District (2,750 spaces, used as recreational space in the off-season), Lot D/South Lot (950 spaces), and the Willets West development (400 spaces) in Phase 1A, and between Lot D/South Lot (5,495 spaces) and the Willets West development (400 spaces) in Phases 1B and 2. Therefore, Mets parking needs would be accommodated.

TRANSIT AND PEDESTRIANS

Significant adverse transit impacts were identified for the street-level stairways and mezzanine stairway on the north side of Roosevelt Avenue at the Mets-Willets Point subway station, line-haul conditions on the No. 7 subway line, ~~train~~ and the Q19, Q48, and Q66 bus routes. In addition, if NYCT reverts back to its pre-CitiField station operating plan for the Mets-Willets Point subway station, which would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day management strategies. However, additional impacts for the station's street-level connections and the unpaid zone passageway could occur during game days with this reconfiguration. Between Draft and Final Supplemental Environmental Impact Statements (SEIS), no changes to operating plans were announced by NYCT; therefore, Hence, any potential changes that may be considered for future implementation will be addressed outside of this environmental review. Significant pedestrian impacts were identified for the east crosswalk at the intersection of Northern Boulevard and 126th Street; the north and west crosswalks at the intersection of Roosevelt Avenue and 126th Street; the north, south, and east crosswalks at the intersection of 34th Avenue and 126th Street; ~~the south crosswalk at the intersection of New Willets Point Boulevard and 126th Street;~~ the north and south crosswalks at the intersection of 37th Avenue and 126th Street; and the north crosswalk at the newly signalized intersection of Roosevelt Avenue and the Lot B driveway. Potential measures to mitigate these projected significant adverse impacts are described in Chapter 21, ~~"Mitigation."~~

B. SUMMARY OF FINDINGS—2008 FGEIS AND SUBSEQUENT TECHNICAL MEMORANDA

The 2008 FGEIS concluded that, of the 29 intersections analyzed, the proposed project and Lot B development were expected to have significant traffic impacts at 21 intersections in the weekday AM peak hour, 17 in the weekday midday peak hour, 23 in the weekday PM peak hour, and 21 in the Saturday midday peak hour on non-game days. During the PM pre-game weekday peak hour there would be significant traffic impacts at 24 intersections and during the Saturday pre-game and post-game peak hours there would be significant impacts at 23 intersections. The subsequent Technical Memoranda concluded that even with changed conditions, new assumptions and new guidance from the *2010 CEQR Technical Manual*, the overall findings of the 2008 FGEIS with regard to significant traffic impacts would remain substantially the same.

Under Phase 2 for the proposed project—representing full buildout conditions—the number of significantly impacted intersections would be approximately the same or somewhat higher as compared to the 2008 FGEIS. The magnitude of delays experienced would be higher at many locations as compared to the 2008 FGEIS. Under Phase 2 for the proposed project, the number of significantly impacted highway sections and ramps, and the magnitude of delays, would generally be higher as compared to the 2008 FGEIS.

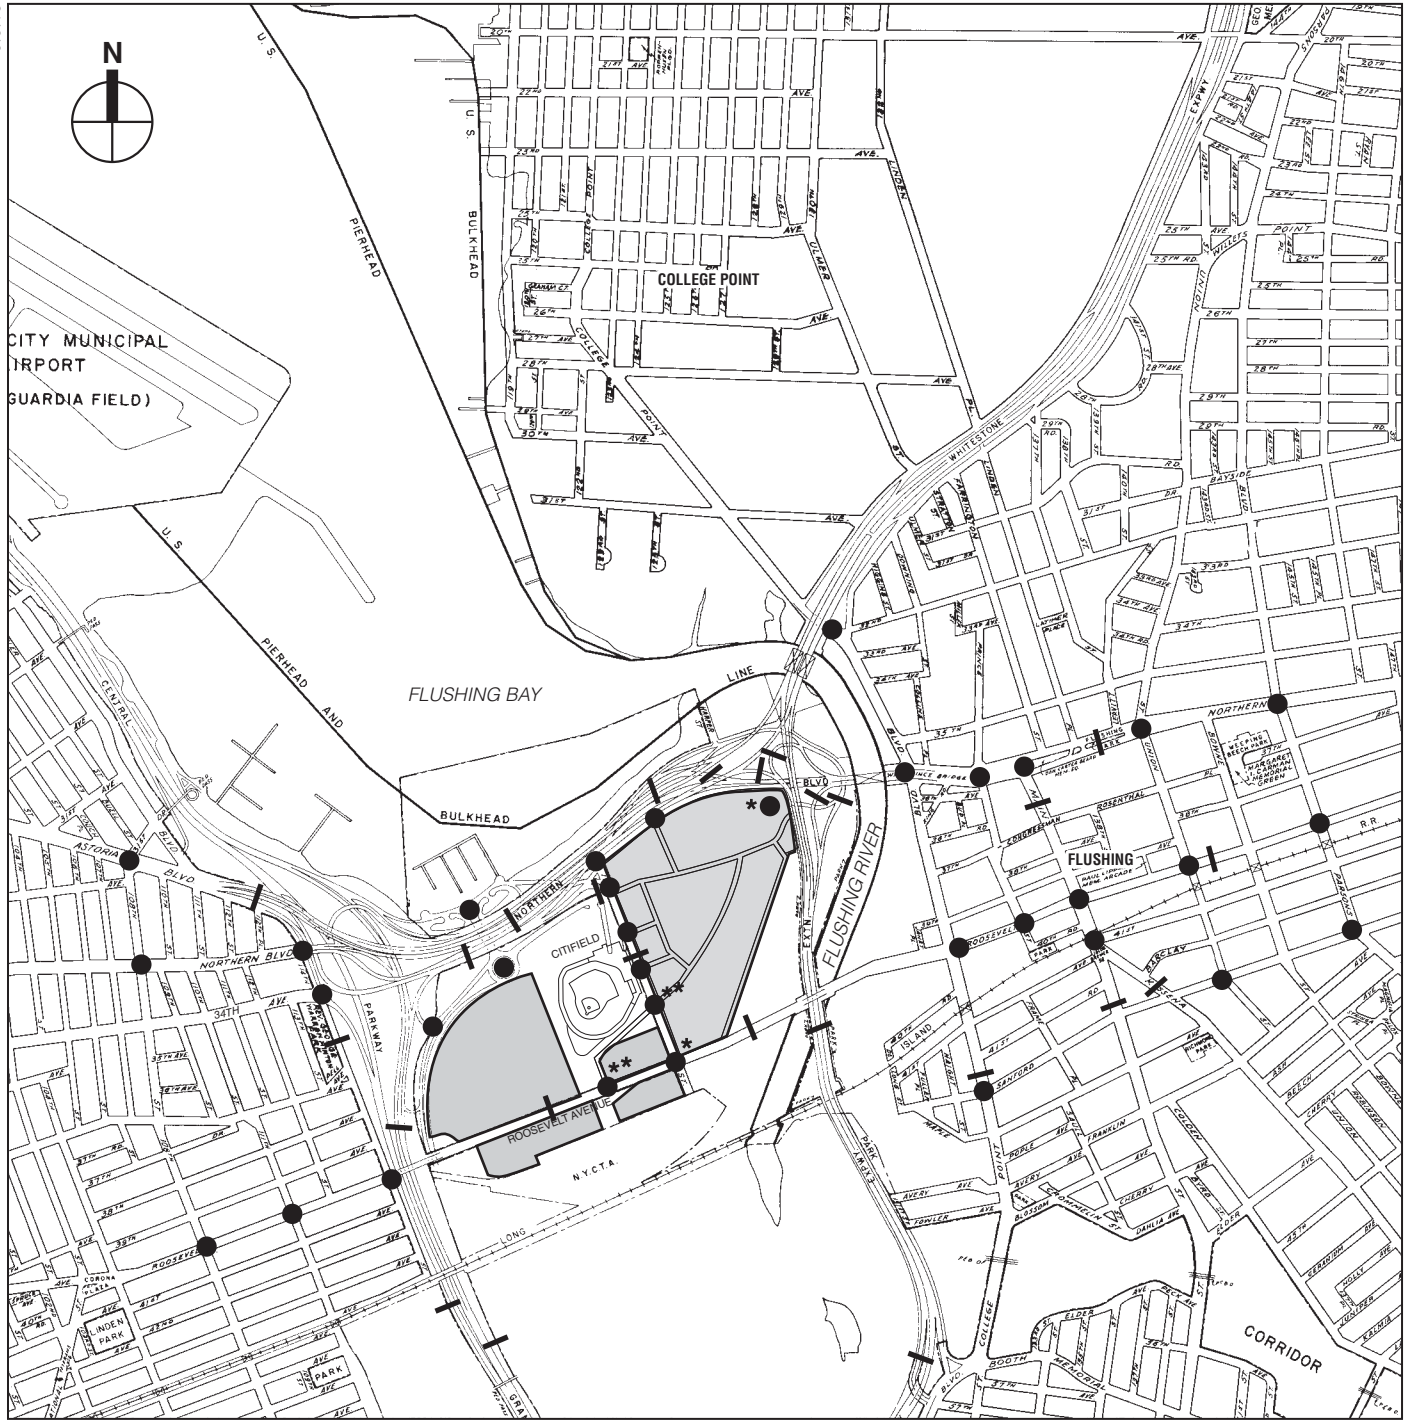

Under Phase 2 for the proposed project, the amount of parking to be provided plus available on-street parking would be sufficient to accommodate the needs of all phases of buildout. The same finding was concluded for the originally proposed project analyzed in the 2008 FGEIS.

For transit and pedestrians, significant adverse impacts were identified in the 2008 FGEIS and subsequent technical memoranda for the Mets-Willets Point subway station, area bus routes, and pedestrian elements adjacent to the District. Similar or greater impacts have been identified for Phase 2 of the proposed project. In addition, the previous analyses did not identify the significant adverse subway line-haul impact or the additional station impacts associated with potential station reconfiguration by NYCT that had been identified with the current proposed project.

C. SCOPE OF ANALYSIS (TRAFFIC AND PARKING)

The traffic and parking analyses cover a large study area encompassing 26 existing signalized intersections and ~~five~~ eight existing unsignalized intersections, ~~plus~~ Of the eight existing unsignalized intersections, two intersections would be signalized in Phase 1A along the District's western boundary at 126th Street and 36th Avenue and 126th Street and 37th Avenue. In Phase 1B, one new signalized another intersection that would be created and signalized, created in Phase 1B along the District's western boundary at 126th Street and Willets Point Boulevard, and another new ~~In Phase 2, the signalized intersection of that would be created in Phase 2 at Roosevelt Avenue and the CitiField/Lot B Internal Street is added for analysis.~~ Key segments of the Grand Central Parkway, Van Wyck Expressway, and Whitestone Expressway, including interchange ramps, have also been studied (see **Figure 14-1**).

The analyses begin with an assessment of existing traffic and parking conditions in the study area, and proceeds to an analysis of conditions in the future without the proposed project (the future No Action condition) for each year of the proposed phased buildout—Phase 1A in 2018, Phase 1B in 2028, and Phase 2 in 2032. The existing and future conditions are analyzed under typical weekday and Saturday peak hour roadway conditions and under roadway conditions typically experienced immediately before and after Mets games on a weekday and Saturday.

Four non-game-day peak hours are analyzed, including the 8:00-9:00 AM weekday morning, 1:00-2:00 PM weekday midday, 5:00-6:00 PM weekday evening, and 1:30-2:30 PM Saturday midday peak hours. Also, three game-day peak hours are analyzed, including the 5:30-6:30 PM pre-game weekday evening, 3:15-4:15 PM pre-game Saturday midday and 7:15-8:15 PM post-game Saturday PM peak hours (i.e., before and after 4 PM Met games). Post-game conditions are not analyzed for a weekday evening game, since project-generated traffic expected during that peak hour would not be significant. All of the analyses of local intersection conditions are based on *2000 Highway Capacity Manual (HCM)* procedures, in accordance with 2012 *City Environmental Quality Review (CEQR) Technical Manual* guidelines. A detailed traffic simulation analysis was also performed using the CORSIM model for the sections of the highway network being analyzed.

The next step in the analyses considers the amount of vehicular traffic expected to be generated by the proposed project in each the three future With Action analysis years and an assessment of future traffic and parking conditions with the proposed project in place (With Action condition). Like the No Action condition, the With Action condition analyzes roadway conditions with and without Mets games, on weekdays, and the weekend. The With Action year analyses identify the locations and extent of significant impacts potentially generated by the proposed project. Traffic improvements that would be needed to mitigate these impacts are identified and evaluated in Chapter 21, “~~Mitigation~~.” The parking analysis addresses the ability of the proposed project to accommodate the parking demands in the With Action years. In addition to the analysis findings presented in this chapter, detailed traffic impact analyses are presented at the end of this chapter and traffic volume maps are presented in **Appendix C**.

D. EXISTING CONDITIONS (TRAFFIC AND PARKING)

ROADWAY NETWORK AND TRAFFIC STUDY AREA

The overall study area generally consists of a grid network of local streets within Downtown Flushing interspersed between Northern Boulevard and Sanford Avenue, as well as a series of intersections along Roosevelt Avenue and Northern Boulevard between 108th and 126th Streets, and along 126th Street between Northern Boulevard and Roosevelt Avenue in Willets Point. There are also additional analysis locations farther away from the immediate study area. The presence of the Grand Central Parkway and the Van Wyck/Whitestone Expressways (both designated as I-678), and the network of ramps and interchanges have a major influence on traffic conditions in the area, since the highways attract a substantial volume of through and destination traffic. Key access points between the local street network and the limited access highways are located along Northern Boulevard, Astoria Boulevard, College Point Boulevard, West Park Loop/Stadium Road, World’s Fair Marina, and 114th Street.

The Van Wyck Expressway is elevated, passing partially over the Flushing River, with three lanes in each direction, and provides a north-south connection from the LIE to where the Van Wyck Expressway becomes the Whitestone Expressway (north of Exit 13), with ramps to/from College Point Boulevard and Northern Boulevard. In particular, the ramps connecting the Van Wyck Expressway with Northern Boulevard provide access, though not completely direct access, to the local street network adjacent to the Special Willets Point District and Willets West portions of the project site.

The Van Wyck Expressway northbound Exit 13W is a single-lane ramp that carries traffic along the eastern and northern boundary of the site, where it joins with an off-ramp from the Whitestone Expressway (southbound Exit 13W) and terminates at a merge with westbound

Northern Boulevard between 126th Place and 126th Street. Because there are no left-turn opportunities from westbound Northern Boulevard past that point, traffic from the northbound Van Wyck Expressway and southbound Whitestone Expressway does not currently have direct access to the project site.

The Grand Central Parkway is an at-grade highway with four lanes typically in each direction; the westbound direction gains an additional lane north of the World's Fair Marina on-ramp. The Grand Central Parkway has a major interchange with the LIE and provides access to Northern Boulevard, Astoria Boulevard, and West Park Loop/Stadium Road. In the eastbound direction, Exit 9E, a two-lane exit ramp, provides access to eastbound Northern Boulevard as well as a route toward the southbound Van Wyck Expressway and northbound Whitestone Expressway. The ramp toward eastbound Northern Boulevard also provides access to 126th Street, touching down at the signalized intersection of 126th Street and 34th Avenue/Stadium Road. The ramp/roadway extending south then east from Exit 9E is joined by a single-lane on-ramp to the eastbound Grand Central Parkway from Astoria Boulevard/114th Street and 34th Avenue.

In the westbound direction, the Grand Central Parkway mainline splits into a pair of two-lane sections immediately upstream of Exit 9P (to Flushing Meadows-Corona Park). The eastern pair provides access to eastbound Northern Boulevard, West Park Loop/Stadium Road, and a route to the Van Wyck/Whitestone Expressway via Exit 9E. The western pair provides access to westbound Northern Boulevard at 114th Street via Exit 9W. North of these exits, the Grand Central Parkway lanes recombine into one mainline section toward LaGuardia Airport.

The local street network throughout the study area is primarily oriented in an east-west direction, with Northern Boulevard and Roosevelt Avenue extending from Corona on the west side to Downtown Flushing east of the Willets Point area. Most of the study area locations are where north-south streets intersect Northern Boulevard and Roosevelt Avenue. Due to the breadth of the study area, roadway characteristics along these roadways can vary, including their width, number of lanes, presence of parking, and adjacent land uses. In addition to Northern Boulevard and Roosevelt Avenue, the other primary east-west streets consist of Kissena Boulevard, Sanford Avenue, 34th Avenue, Astoria Boulevard, and West Park Loop/Stadium Road, as described below.

- Northern Boulevard is a primary east-west arterial across the study area, carrying significant traffic volumes to and from the Grand Central Parkway and Van Wyck Expressway, as well as through traffic toward western Queens and Manhattan. Its geometric and traffic characteristics vary throughout the study area. Through Downtown Flushing (between Prince Street and Parsons Boulevard) and Corona (between 108th Street and 114th Street), Northern Boulevard is a multilane roadway with curbside parking and is predominantly undivided except for a section between Prince Street and Union Street, where the roadway's east and west travel directions are separated by a wide landscaped median. Immediately west of Prince Street, the mainline section of Northern Boulevard transitions into a viaduct over the Flushing River, flanked by service roads to and from College Point Boulevard. The section of Northern Boulevard between 114th Street and Prince Street is generally a highway-type roadway with ramps to/from the Grand Central Parkway and Van Wyck Expressway; there is limited curbside parking and only one intermediate traffic signal, at the intersection with 126th Street.
- Roosevelt Avenue extends east-west through the entire study area from Corona to Flushing, carrying moderate traffic volumes. Between 108th and 114th Streets, Roosevelt Avenue has one moving lane in each direction with curbside parking, but east of 114th Street it changes

to two moving lanes per direction and with no parking up to College Point Boulevard. For most of this segment, the roadway is straddled by the elevated No. 7 subway line until the train moves underground after passing the Flushing River. Through Downtown Flushing, Roosevelt Avenue has generally one moving lane per direction with a mix of parking, MTA bus stops and layover zones, and other curbside activities.

- Sanford Avenue study locations are situated within Downtown Flushing, where the roadway operates one-way westbound from Kissena Boulevard to College Point Boulevard and two-way from Kissena Boulevard to Parsons Boulevard. The one-way segment typically operates with two moving lanes, while the two-way section has one to two lanes in each direction.
- 34th Avenue is discontinuous between 114th Street and 126th Street, and its intersection with 114th Street serves as a primary access point to the eastbound Grand Central Parkway. West of 114th Street, the roadway is two-lane and bi-directional, and where it continues east of 126th Street through the District, its condition is in general disrepair, with very low traffic volumes.
- Astoria Boulevard, like Northern Boulevard, is a major east-west arterial that carries significant traffic volumes between the study area—particularly the highway network—and northwestern Queens and the RFK/Triboro Bridge. In the eastbound direction, the roadway terminates at its ramps toward the Grand Central Parkway and the Van Wyck/Whitestone Expressway. Through North Corona on the west side of the study area, Astoria Boulevard is divided by a raised median, with multiple lanes in each direction and curbside parking.
- West Park Loop/Stadium Road is a limited access roadway along the west and north boundaries of the CitiField parking lots. Due to its direct ramps to and from the westbound Grand Central Parkway at Exit 9E, the roadway experiences the heaviest volumes before and after Mets games; otherwise, it does not have much traffic. West of the intersection at Boat Basin Road, West Park Loop/Stadium Shea Road has two lanes in each direction, divided by a landscaped median; the roadway is undivided to the east up to 126th Street.

The primary north-south cross-streets, which consist of College Point Boulevard, Main Street, Parsons Boulevard, and 108th Street, provide access to Northern Boulevard and Roosevelt Avenue from neighborhoods north and south of Downtown Flushing and Corona as well as the LIE. The remaining north-south streets, which carry less traffic and/or provide less regional access for though traffic, include Prince Street, Union Street, 111th Street, 114th Street, and 126th Street.

- College Point Boulevard is a bi-directional, multi-lane roadway between the LIE, south of the study area, to College Point, north of Downtown Flushing. The roadway serves as the link between the westbound LIE and the Van Wyck Expressway, since there are no direct interchange ramps between them. Due to highway access and adjacent land uses, College Point Boulevard carries both significant auto volumes and moderate to high truck traffic.
- Main Street extends through the core of Downtown Flushing, terminating at Northern Boulevard from the LIE and neighborhoods to the south, and serves as a primary MTA bus transit corridor. Although the roadway generally has two moving lanes in each direction and traffic volumes are moderate, the mix of bus traffic and the frequency of stops, parking and other curbside activities, and pedestrian crossings impact capacity.
- Kissena Boulevard is a northwest-southeast oriented street that approaches Downtown Flushing from areas to the south, terminates at Main Street within the downtown core near the Long Island Rail Road (LIRR) trestle, and serves as another primary MTA bus transit

corridor to and from the south. Kissena Boulevard generally has one to two lanes in each direction with moderate volumes, but it also suffers from the same capacity hindrances as Main Street in the immediate Downtown Flushing area.

- Union Street connects to Northern Boulevard and Roosevelt and Sanford Avenues, and carries moderate traffic volumes through Downtown Flushing. Union Street also serves as a primary access and egress route for Municipal Lot No. 1. Its cross-section width varies with one or two moving lanes in each direction, and curbside parking is typical north of Roosevelt Avenue.
- Parsons Boulevard extends parallel to Main and Union Streets through Downtown Flushing and is primarily a residential street through the study area, with low to moderate volumes. It also connects to Northern Boulevard and Roosevelt and Sanford Avenues, and has one moving lane in each direction with curbside parking.
- 108th Street has one moving lane in each direction through the study area, with curbside parking. It extends through Roosevelt Avenue and Northern and Astoria Boulevards, providing access to residential blocks in the neighborhood of Corona, and carries low to moderate traffic volumes.
- Prince Street is a minor two-way, two-lane street within Downtown Flushing carrying low traffic volumes. It connects to Roosevelt Avenue and Northern Boulevard, as well as some cross-streets through the downtown area.
- 111th Street is one-way northbound through the neighborhood of Corona, providing access to Northern Boulevard from Roosevelt Avenue. Across a number of residential blocks, it has one moving lane with curbside parking in each direction and carries low to moderate traffic volumes.
- 114th Street is typically two-way, except for the blocks between 112th Street and 34th Avenue, where it is one-way southbound only. The roadway provides access to the ramp to the eastbound Grand Central Parkway at 34th Avenue; it carries high volumes of traffic southbound from Northern Boulevard to the on-ramp. Between 34th and Roosevelt Avenues, 114th Street is two-way, with one lane typical in each direction, and carries lower volumes.
- 126th Street forms the boundary between CitiField and the Special Willets Point District. This two-way roadway generally has two moving lanes in each direction and carries low volumes, although the high number of parking maneuvers due to land uses along the east side of the street affects capacity. During the hours before and after Mets games, traffic volumes and queuing along 126th Street are significantly higher. The southern end of 126th Street at Roosevelt Avenue also serves as the entrance/exit to the Casey Stengel bus depot and the Corona subway yard, where bus and employee access to these facilities are provided.

The traffic study area developed for this ~~Final SEIS Supplemental Environmental Impact Statement (SEIS)~~ includes the following 34 ~~34~~ intersections, which are also shown in **Figure 14-1** (all intersections are signalized unless otherwise noted)

- 108th Street at Astoria Boulevard
- 108th Street at Northern Boulevard
- 114th Street at Northern Boulevard
- 126th Street at Northern Boulevard
- Prince Street at Northern Boulevard

Willets Point Development

- Main Street at Northern Boulevard
- Union Street at Northern Boulevard
- Parsons Boulevard at Northern Boulevard
- 114th Street at 34th Avenue
- 126th Street at 34th Avenue
- 108th Street at Roosevelt Avenue
- 111th Street at Roosevelt Avenue
- 114th Street at Roosevelt Avenue
- 126th Street at Roosevelt Avenue
- College Point Boulevard at Roosevelt Avenue
- Prince Street at Roosevelt Avenue
- Main Street at Roosevelt Avenue
- Union Street at Roosevelt Avenue
- Parsons Boulevard at Roosevelt Avenue
- Main Street at Kissena Boulevard
- College Point Boulevard at Sanford Avenue
- Union Street at Sanford Avenue
- Parsons Boulevard at Sanford Avenue
- College Point Boulevard at 32nd Avenue/Whitestone Expressway Service Road
- College Point Boulevard at Northern Boulevard Service Road
- Boat Basin Road at Stadium Road
- Northern Boulevard at 126th Place (unsignalized)
- 126th Street at 36th Avenue (unsignalized)
- 126th Street at 37th Avenue (unsignalized)
- Willets Point Boulevard at 126th Street (unsignalized)
- Boat Basin Road at World's Fair Marina (unsignalized)
- Willets Point Boulevard at Northern Boulevard (unsignalized)
- Boat Basin Road at Stadium Road/CitiField Entrance 8 (unsignalized)
- Grand Central Parkway westbound exit ramp at West Park Loop/Stadium Road (unsignalized).

One additional intersection created by the design of the proposed project along 126th Street (New Willets Point Boulevard at 126th Street) is analyzed under the With Action condition for Phases 1B and 2, and ~~another one additional~~ intersection created along Roosevelt Avenue (CitiField/Lot B Internal Street at Roosevelt Avenue) is analyzed under Phase 2 only. ~~In addition to the study locations listed above, the intersections of 126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place are expected to carry a significant amount of project-generated trips in all three buildout phases of the proposed project. These three unsignalized intersections were not analyzed for this Draft SEIS since the majority of project-generated trips from the District were assigned to the adjacent analyzed intersections.~~

However, as further discussed in Chapter 21, “Mitigation,” because impacts have been identified for these adjacent intersections, the three intersections listed above will be analyzed for the Final SEIS to determine if they would similarly experience significant adverse impacts. For this Final SEIS, the intersections of 126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place were analyzed since they are expected to carry a significant amount of project-generated trips in all three buildout phases. The intersections of 126th Street at 36th Avenue and 126th Street at 37th Avenue would be signalized under all three phases of the proposed project.

Sections of the highway network are also analyzed, including:

- Grand Central Parkway mainline in both directions between the LIE and Roosevelt Avenue
- Van Wyck Expressway mainline in both directions between the LIE and Roosevelt Avenue
- Whitestone Expressway mainline in both directions between Northern Boulevard and Linden Place
- Ramp from World’s Fair Marina/Boat Basin Road to the Grand Central Parkway
- Ramps from the northbound Van Wyck Expressway to eastbound and westbound Northern Boulevard
- Ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway
- Ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway
- Ramp from eastbound Astoria Boulevard and eastbound Northern Boulevard to the northbound Whitestone Expressway
- Ramps from the southbound Whitestone Expressway to the eastbound and westbound Grand Central Parkway
- Ramp from westbound Northern Boulevard and southbound Whitestone Expressway to westbound Astoria Boulevard
- Ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard
- Ramp from the eastbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway
- Ramp from the southbound Whitestone Expressway to westbound Northern Boulevard

Two additional ramps to and from the Van Wyck Expressway proposed at the northern end of Willets Point Boulevard are analyzed reflected under With Action conditions (for Phases 1B and 2).

EXISTING TRAFFIC VOLUMES AND LEVELS OF SERVICE

For continuous traffic data collection, 24-hour Automatic Traffic Recorders (ATRs) were installed along selected local streets, ramps, and expressway mainlines during the periods of May 5 to May 20, 2012. Concurrent manual turning movement counts (TMCs) were conducted for a typical weekday with no Mets home game, a Saturday with no Mets home game, weekday pre-game conditions, and weekend pre- and post-game conditions. The weekend Mets game began 4:05 PM (on May 5, 2012), and the weeknight game began at 7:10 PM (on May 16, 2012). The Mets game attendance on the weeknight and weekend afternoon that traffic volumes were collected was 22,659 and 30,253, respectively, which is lower than that of a typical game day. In order to adjust volumes to account for more typical game days, attendance data were

collected for all games from the previous two seasons (2010 and 2011). The 85th percentile attendance for weekday games for the 2010 and 2011 seasons combined was 35,914 attendees; the 85th percentile attendance for weekend games for the 2010 and 2011 seasons combined was 37,577 attendees. The differences in attendees were developed into additional vehicle trips and assigned through the study network based on modal split, temporal distribution, and vehicle occupancy factors, and trip assignment assumptions from the *Shea Stadium Redevelopment FEIS* (2001). The resulting volumes together with the turning movement counts were used to develop existing game day traffic volumes. This methodology was approved by the New York City Department of Transportation (NYCDOT). The existing volumes were used, along with observations of actual traffic conditions, to determine the seven peak traffic analysis hours. **Tables 14-1** and **14-2** summarize the analysis time periods.

Table 14-1
Traffic Study Peak Hours—Without Mets Game

Day	Time	Peak Hour
Weekday	8:00-9:00 AM	Non-game AM
	1:00-2:00 PM	Non-game midday
	5:00-6:00 PM	Non-game PM
Saturday	1:30-2:30 PM	Non-game midday

Table 14-2
Traffic Study Peak Hours—With Mets Game

Day	Time	Peak Hour
Weekday	5:30-6:30 PM	Pre-game PM arrival peak
Saturday	3:15-4:15 PM	Pre-game afternoon arrival peak
	7:15-8:15 PM	Post-game PM departure peak

Without a Mets home game at CitiField:

- Weekday AM peak hour (8:00 AM – 9:00 AM)
- Weekday midday peak hour (1:00 PM – 2:00 PM)
- Weekday PM peak hour (5:00 PM – 6:00 PM)
- Saturday midday peak hour (1:30 PM – 2:30 PM).

With a Mets home game at CitiField:

- Weekday PM peak hour pre-game arrivals (5:30 PM – 6:30 PM)
- Weekend midday peak hour pre-game arrivals (3:15 PM – 4:15 PM)
- Weekend late afternoon peak hour post-game departures (7:15 PM – 8:15 PM).

The operation of all of the signalized and unsignalized intersection analysis locations were assessed using methodologies presented in the *2000 Highway Capacity Manual (HCM)* using the *Highway Capacity Software (HCS+ 5.5)*, which is the analysis methodology approved for use by NYCDOT. The *HCM* procedure evaluates the levels of service (LOS) for signalized and unsignalized intersections using average stop control delay, in seconds per vehicle, as described below.

SIGNALIZED INTERSECTIONS

The average control delay per vehicle is the basis for determining levels of service for individual lane groups (grouping of movements in one or more travel lanes), the overall approaches to each intersection, and the overall intersection itself. Levels of service are defined in **Table 14-3**.

LOS A describes operations with low delays, i.e., an average control delay of 10.0 seconds or less per vehicle. This occurs when signal progression is extremely favorable and most vehicles arrive during the green phase. Most vehicles do not stop at all.

Table 14-3
LOS Criteria for Signalized Intersections

LOS	Average Control Delay
A	≤ 10.0 seconds
B	>10.0 and ≤ 20.0 seconds
C	>20.0 and ≤ 35.0 seconds
D	>35.0 and ≤ 55.0 seconds
E	>55.0 and ≤ 80.0 seconds
F	>80.0 seconds
Source: Transportation Research Board. <i>Highway Capacity Manual</i> , 2000.	

LOS B describes operations with delays in excess of 10.0 seconds up to 20.0 seconds per vehicle. This generally occurs with good progression and/or short cycle lengths. Again, most vehicles do not stop at the intersection.

LOS C describes operations with delays in excess of 20.0 seconds up to 35.0 seconds per vehicle. These higher delays may result from fair progression and/or longer cycle lengths. The number of vehicles stopping is noticeable at this level, although many still pass through the intersection without stopping.

LOS D describes operations with delays in excess of 35.0 seconds up to 55.0 seconds per vehicle. At LOS D, the influence of congestion becomes more noticeable. Longer delays may result from some combination of unfavorable progression, long cycle lengths, or high volume-to-capacity (v/c) ratios. Many vehicles stop, and the proportion of vehicles not stopping declines.

LOS E describes operations with delays in excess of 55.0 seconds up to 80.0 seconds per vehicle. These high delay values generally indicate poor progression, long cycle lengths, and high v/c ratios.

LOS F describes operations with delays in excess of 80.0 seconds per vehicle. This is considered to be unacceptable to most drivers. This condition often occurs with oversaturation, i.e., when arrival flow rates exceed the capacity of the intersection. It may also occur at high v/c ratios with cycle failures. Poor progression and long cycle lengths may also contribute to such delays. Often, vehicles do not pass through the intersection in one signal cycle.

Based on *CEQR Technical Manual* guidelines, LOS A, B, and C are considered acceptable, LOS D is considered marginally acceptable up to mid-LOS D (45 seconds of delay for signalized intersections) and unacceptable above mid-LOS D, and LOS E and F indicate congestion. These guidelines are applicable to individual traffic movements and overall intersection levels of service.

UNSIGNALIZED INTERSECTIONS

For unsignalized intersections, the average control delay is defined as the total elapsed time from which a vehicle stops at the end of the queue until the vehicle departs from the stop line. The level of service criteria for unsignalized intersections are summarized in **Table 14-4**.

For unsignalized intersections, LOS E is considered the limit of acceptable delay, while LOS F is considered unacceptable to most drivers. LOS F conditions exist when there are insufficient gaps of suitable size in a major vehicular traffic stream to allow side street traffic to cross safely.

Table 14-4
LOS Criteria for Unsignalized Intersections

LOS	Average Control Delay
A	≤ 10.0 seconds
B	> 10.0 and ≤ 15.0 seconds
C	> 15.0 and ≤ 25.0 seconds
D	> 25.0 and ≤ 35.0 seconds
E	> 35.0 and ≤ 50.0 seconds
F	> 50.0 seconds
Source: Transportation Research Board. <i>Highway Capacity Manual</i> , 2000.	

Tables 14-5 and **14-6** provide an overview of the levels of service of the overall intersections and the individual lane groups (i.e., set[s] of lanes established at an intersection approach for discrete capacity and level of service analysis), respectively, that characterize the traffic study area during the peak hours. A summary description is also provided below:

- All 26 signalized intersections operate at overall LOS D or better during all seven peak hours. “Overall” LOS E or F would mean that serious congestion exists—either one specific traffic lane group has severe delays, or two or more of the specific traffic lane groups at the intersection are at LOS E or F with very significant delays (the overall intersection LOS is a weighted average of all of the individual traffic lane groups).
- During the non-game weekday AM peak hour, four signalized intersections operate at overall LOS D. Thirteen specific lane groups (e.g., a shared left turn-through-right turn, an exclusive left turn lane, etc.) out of approximately 127 total lane groups analyzed are at LOS E or F conditions.
- In the non-game weekday midday peak hour, three signalized intersections operate at overall LOS D. Eight lane groups operate at LOS E.
- In the non-game weekday PM peak hour four signalized intersections operate at overall LOS D. Thirteen lane groups have overall unacceptable LOS E.
- In the non-game Saturday midday peak hour, four signalized intersections operate at overall LOS D. Eleven lane groups operate at LOS E.
- In the pre-game weekday PM arrival peak hour, six signalized intersections operate at overall LOS D. Sixteen lane groups operate at LOS E or F.
- In the pre-game Saturday midday arrival peak hour, six signalized intersections operate at overall LOS D. Eighteen lane groups operate at LOS E or F.
- In the post-game Saturday weekend PM departure peak hour, five signalized intersections operate at overall LOS D. Sixteen lane groups operate at LOS E or F.

- Generally, the five eight unsignalized intersections operate at overall acceptable levels of service during the four non-game peak hours and the weekday PM pre-game condition. However, during the weekend pre-game arrival peak, one intersection, Boat Basin Road at Stadium Road/CitiField Entrance, operates at overall unacceptable LOS E, with one lane group at LOS F. During the weekend post-game departure peak, the intersection of Boat Basin Road at World's Fair Marina, operates at overall unacceptable LOS E (with one lane group at LOS F), and the intersection of Boat Basin Road at Stadium Road/CitiField Entrance operates at overall LOS F (with two lane groups at LOS E or F).

Table 14-5

Existing Overall Intersection Level of Service Summary

Signalized Intersections (26 Total)	Non-Game Day				Game Day		
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Pre-game Weekday PM	Pre-game Saturday Midday	Post-game Saturday PM
Overall Intersection LOS A/B/C	22	23	22	22	20	20	21
Overall Intersection LOS D	4	3	4	4	6	6	5
Overall Intersection LOS E	0	0	0	0	0	0	0
Overall Intersection LOS F	0	0	0	0	0	0	0
Note: During the non-game and weekday pre-game peak hours, all <u>five eight</u> unsignalized intersections operate at overall LOS A, B, C, or D; during the weekend pre-game peak hour, Boat Basin Road at Stadium Road/CitiField Entrance 8 operates at LOS E; during the weekend post-game peak period, Boat Basin Road at World's Fair Marina operates at overall LOS E and Boat Basin Road at Stadium Road/CitiField Entrance 8 operates at LOS F.							

Table 14-6

Existing Traffic Lane Group Level of Service Summary

Signalized Lane Groups (Approx. 127 Total)	Non-Game Day				Game Day		
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Pre-game Weekday PM	Pre-game Saturday Midday	Post-game Saturday PM
Number of Lane Groups at LOS A/B/C	80	97	86	88	76	90	89
Number of Lane Groups at LOS D	34	24	30	30	37	21	25
Number of Lane Groups at LOS E	10	8	13	11	15	16	15
Number of Lane Groups at LOS F	3	0	0	0	1	2	1
Note: During the non-game peak hours, all unsignalized lane groups operate at LOS A, B, C or D; during the weekday pre-game peak hour, northbound left turns from Boat Basin Road onto World's Fair Marina operate at LOS E; during the weekend pre-game peak period, the eastbound left-through movement of Boat Basin Road at Stadium Road operates at LOS F; during the weekend post-game period, northbound left turns from Boat Basin Road onto World's Fair Marina operate at LOS F, eastbound Stadium Road at Boat Basin Road operates at LOS F, westbound CitiField Entrance 8 at Boat Basin Road operates at LOS E, and eastbound left turns from the GCP off-ramp onto Stadium Road operates at LOS E.							

A more detailed presentation of traffic volumes and levels of service by corridor are provided below. (Detailed level of service analysis results, including results for every traffic lane group at each of the intersections analyzed, appear at the end of this chapter. Detailed traffic volume maps are presented in **Appendix C**).

NORTHERN BOULEVARD

Through Downtown Flushing, Northern Boulevard is traveled by approximately 800–1,550 vehicles per hour (vph) in the eastbound direction and 1,675–2,325 vph in the westbound direction during the weekday AM peak hour on non-game days. Since westbound is the prevailing travel direction in the weekday AM peak hour, westbound volumes generally build through Downtown Flushing toward the ramps to the Van Wyck Expressway and the Grand Central Parkway. Adjacent to the Special Willets Point District and Willets West portions of the project site, Northern Boulevard carries approximately 325–1,025 vph and 950–2,075 vph in the eastbound and westbound directions, respectively. At the intersection with 126th Street, 1,050 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and 625 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 900 and 2,000 vph, respectively.

During the weekday midday peak hour on non-game days, there are approximately 950–1,600 vph in the eastbound direction and 1,050–1,825 vph in the westbound direction on Northern Boulevard through Downtown Flushing. Northern Boulevard carries approximately 425–1,150 vph and 425–1,300 vph in the eastbound and westbound directions, respectively, adjacent to the project site. At the intersection with 126th Street, approximately 700 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and about 600 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 1,000 and 1,125 vph, respectively.

During the weekday PM peak hour on a non-game day, Northern Boulevard is traveled by approximately 1,400–2,050 vph in the eastbound direction and 1,150–1,675 vph in the westbound direction through Downtown Flushing. Adjacent to the project site, Northern Boulevard carries approximately 600–1,525 vph and 575–1,575 vph in the eastbound and westbound directions, respectively. At the intersection with 126th Street, approximately 830 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and approximately 800 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 1,750 and 1,525 vph, respectively.

During the Saturday midday peak hour on a non-game day, there are approximately 1075–1,800 vph in the eastbound direction and 1,325–1,945 vph in the westbound direction on Northern Boulevard through Downtown Flushing. Northern Boulevard carries approximately 475–1,250 vph and 450–1,425 vph in the eastbound and westbound directions, respectively, adjacent to the Special Willets Point District and CitiField. At the intersection with 126th Street, 750 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and approximately 650 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 1,125 and 1,775 vph, respectively.

During the weekday PM pre-game arrival peak hour, eastbound volumes on Northern Boulevard are approximately 1,400–2,075 vph through Downtown Flushing, generally similar to those on

non-game days. Westbound volumes are approximately 1,300–1,750 vph, slightly higher than on non-game days, which is expected due to increased traffic toward CitiField. Adjacent to the project site in the vicinity of 126th Street, Northern Boulevard eastbound volumes are approximately 575–1,675 vph; westbound volumes are approximately 725–2,525 vph. At the intersection with 126th Street, approximately 1,570 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and about 950 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. The New York City Police Department (NYPD) channelizes and operates the one-lane ramp and the adjacent lane (right lane) of Northern Boulevard as free-flow through the traffic signal at 126th Street so that it is able to process the heavy pre-game volume. Much of this traffic immediately exits Northern Boulevard onto the slip ramp to World's Fair Marina to access stadium parking lots. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 1,750 and 1,625 vph, respectively.

During the weekend afternoon pre-game arrival peak hour, there are approximately 1,150–1,800 vph in the eastbound direction and 1,250–1,925 vph in the westbound direction on Northern Boulevard through Downtown Flushing. Northern Boulevard carries approximately 300–1,175 vph and 525–2,175 vph in the eastbound and westbound directions, respectively, adjacent to the project site. At the intersection with 126th Street, approximately 1,350 vph enter westbound Northern Boulevard from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway, and approximately 1,030 vph enter eastbound Northern Boulevard from the Grand Central Parkway/Astoria Boulevard ramp. Again, NYPD operates the ramp similarly to the weekday PM pre-game condition, since a large portion of the entering traffic immediately exits to World's Fair Marina. Northern Boulevard eastbound and westbound volumes in the vicinity of 108th and 114th Streets are approximately 1,250 and 1,500 vph, respectively.

During the weekend PM post-game departure peak hour, there are approximately 1,250–1,875 vph in the eastbound direction and 1,150–1,700 vph westbound direction on Northern Boulevard through Downtown Flushing. Northern Boulevard carries approximately 350–1,275 vph and 450–1,650 vph in the eastbound and westbound directions, respectively, adjacent to the project site. The significant volume sources to westbound Northern Boulevard during this time period is 126th Street, carrying about 800 vph of departure traffic from CitiField parking lots, and the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway carrying about 600 vph. In the eastbound direction, the ramp from the Grand Central Parkway/Astoria Boulevard adds approximately 980 vph onto Northern Boulevard. Volumes along Northern Boulevard in the vicinity of 108th and 114th Streets are approximately 1,125 vph in the eastbound direction and 1,475 vph traveling westbound.

Traffic movements with high volumes and/or critical levels of service on Northern Boulevard during one or more analysis time period(s) include: the westbound through movement at 126th Street from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway; eastbound and westbound mainline left turns at Prince Street; eastbound right turns at Main Street; and the westbound through/right turn movement at Parsons Boulevard. These movements sometimes experience significant delays, including unacceptable LOS D (delays above mid-D), E or F, due to heavy volumes and over-saturated conditions. The Northern Boulevard westbound left turn onto Prince Street, though a low volume, typically experiences LOS E or F conditions due to the small portion of effective green time it receives out of the long signal cycle. Importantly, the overall intersection levels of service for Northern

Boulevard intersections, which are based on a weighted average of the delays for all of the traffic movements at each intersection, are greatly dependent on the delays of the high-volume eastbound and westbound through movements, even though the delays of Northern Boulevard turn movements and cross-street movements are generally worse.

For non-game day conditions, overall levels of service at intersections along Northern Boulevard between 108th Street and Prince Street are generally acceptable LOS B or C. The intersection of Northern Boulevard at 108th Street operates at overall marginally acceptable LOS D during the Saturday midday peak hour. Overall, Northern Boulevard at its intersections with Main Street, Prince Street, Union Street and Parsons Boulevard operate at marginally acceptable LOS D or better. Northern Boulevard at Parsons Boulevard operates at overall marginally unacceptable LOS D during the Saturday midday peak hour.

For game-day conditions, all Northern Boulevard intersections in the vicinity of the project site and to the west operate at overall LOS C or better. As mentioned above, NYPD traffic demand management at the intersection of Northern Boulevard and 126th Street allows free-flow operation of the westbound through movement from the ramp connection from the southbound Whitestone Expressway and northbound Van Wyck Expressway during pre-game periods. This generally helps process traffic from the ramp improving the overall traffic flow around the project site and CitiField.

All Northern Boulevard intersections in Downtown Flushing operate at overall LOS C or marginally acceptable LOS D (delays below mid-D) during the three game-day peak hours.

ROOSEVELT AVENUE

Through Downtown Flushing, Roosevelt Avenue is traveled by approximately 150–650 vph in the eastbound direction and 200–450 vph in the westbound direction during the non-game day peak hours. The highest eastbound volumes through the downtown area occur approaching Prince Street, while the highest westbound volumes are at the intersections with Union Street and Prince Street. Adjacent to the project site, in the vicinity of 126th Street to 114th Street, eastbound volumes on Roosevelt Avenue are approximately 425–750 vph, while the westbound flow is approximately 450–800 vph for non-game day conditions. Between 108th and 114th Streets, volumes are approximately 300–475 vph eastbound and 375–600 vph westbound.

During the game-day peak hours, there are approximately 150–675 vph per direction on Roosevelt Avenue through Downtown Flushing. Adjacent to the project site, in the vicinity of 126th Street to 114th Street, eastbound volumes on Roosevelt Avenue are approximately 500–850 vph, while westbound volumes are approximately 725–1,150 vph for the pre-game conditions. Weekend post-game volumes along the same section of Roosevelt Avenue are approximately 450–750 vph eastbound and 450–950 vph westbound. Also during the weekend PM post-game departure peak hour, there are up to 975 vph on eastbound Roosevelt Avenue approaching College Point Boulevard, much of this as departing game traffic. Between 108th and 114th Streets, volumes are approximately 400–600 vph per direction during pre-game peak hours, and approximately 350–500 vph per direction during the post-game peak hour.

For non-game conditions, overall intersection levels of service along Roosevelt Avenue are at acceptable LOS C or better except at the intersections of Roosevelt Avenue at College Point Boulevard and Roosevelt Avenue and Main Street which operate at overall marginally acceptable LOS D during the weekday PM peak hour, and at the intersection of Roosevelt Avenue at Parsons Boulevard which operates at marginally acceptable LOS D during the weekday AM peak hour. All individual traffic movements along Roosevelt Avenue operate at

acceptable or marginally acceptable levels of service (below mid-D) except at Main Street where westbound Roosevelt Avenue operates at unacceptable LOS D in the weekday AM peak hour and westbound and eastbound Roosevelt Avenue operate at LOS E in weekday PM peak hour. Traffic conditions through Main Street tend to be the most problematic along the corridor due to the heavy bus and pedestrian activity at the intersection, which is the nexus of Downtown Flushing's inter-modal transportation hub.

During game-day conditions, all intersections along Roosevelt Avenue within the vicinity of the project site operate at overall marginally acceptable LOS D or better during all peak hours. Also, all individual lane groups on Roosevelt Avenue operate at acceptable LOS C or better. The increase in volumes along Roosevelt Avenue during game-day peak hours due to traffic demand to CitiField is managed by NYPD to optimize traffic flow. At the intersection of Roosevelt Avenue and 126th Street, effective green times are adjusted, with preference to the eastbound left-turn movement (toward the CitiField parking lots north of Roosevelt Avenue) and to the southbound right-turn movement (towards the south parking lots). During the weekend post-game peak hour, NYPD continues to manage the Roosevelt Avenue/126th Street intersection, especially to process the eastbound through and southbound left turn movements carrying traffic out of these lots. Overall, the post-game demand management along Roosevelt Avenue adjacent to CitiField and the project site is effective.

Concurrently, the Roosevelt Avenue intersections through Downtown Flushing all operate at overall acceptable LOS C and marginally acceptable LOS D except for Roosevelt Avenue at College Point Boulevard which operates at overall unacceptable LOS D during the weekday pre-game peak hour. The Roosevelt Avenue eastbound shared through-right movement at this intersection operates at unacceptable LOS D or LOS E during pre-game and post-game peak hours. The only other traffic movement which operates at unacceptable levels of service during game day peak hours is eastbound Roosevelt Avenue approaching Main Street which operates at LOS E during the weekday pre-game peak hour.

KISSENA BOULEVARD

Kissena Boulevard, in the vicinity of Main Street, is traveled by approximately 200–350 vph per direction during all non-game and game day peak hours. Kissena Boulevard also carries significant bus traffic along seven bus routes to and from Main Street, with up to approximately 65 buses per hour per direction. The intersection of Kissena Boulevard and Main Street operates at overall acceptable LOS C during all non-game and game day peak hours. The Kissena Boulevard approach at Main Street operates at marginally acceptable LOS D (below mid-D) or better during all analysis periods, both for non-game and game conditions.

SANFORD AVENUE

Analysis locations along Sanford Avenue are located within Downtown Flushing, where traffic volumes are approximately 175–275 vph in the eastbound direction and 275–475 vph in the westbound direction during the non-game day peak hours. During the game-day peak hours, there are approximately 175–275 vph and 300–675 vph traveling eastbound and westbound, respectively, on Sanford Avenue through Downtown Flushing. During all of the analysis peak hours, the three intersections analyzed along Sanford Avenue operate at overall acceptable LOS B or C.

34TH AVENUE

As stated previously, 34th Avenue is discontinuous within the study area between 114th and 126th Streets. East of 126th Street, through the Special Willets Point District, 34th Avenue is traveled by only approximately 50–150 vph in each direction during all non-game and game day peak hours. West of 114th Street, 34th Avenue serves as an access route to the Grand Central Parkway eastbound on-ramp, where it carries approximately 350–525 vph eastbound and 50–125 vph westbound.

During pre-game conditions, NYPD manages the intersection of 34th Avenue at 126th Street and Stadium Road, including the at-grade ramp from Northern Boulevard and the elevated access ramp from the Grand Central Parkway/Astoria Boulevard. NYPD management includes: (1) deactivation of the traffic signal; (2) traffic cone/barrier channelization of the southbound Grand Central Parkway ramp to allow for two lanes. During the weekend post-game peak hour, NYPD traffic management includes the deactivation of the traffic signal.

Both 34th Avenue analysis locations operate at overall acceptable levels of service or marginally acceptable LOS D during all non-game peak hours. During game-day peak hours, the intersection of 34th Avenue and 114th Street operates at similar overall levels of service, while the intersection of the 126th Street/GCP Ramp at 34th Avenue operates at overall marginally unacceptable LOS D during all game-day peak hours. The only individual movement on 34th Avenue that operates at unacceptable levels of service is westbound 34th Avenue approaching 126th Street which operates at marginally unacceptable LOS D during all non-game peak hours and at LOS E during the Saturday pre-game peak hour.

Levels of service for both 34th Avenue analysis locations operate at overall acceptable levels of service and marginally acceptable LOS D during all non-game peak hours. During game-day peak hours, the intersection of 34th Avenue and 114th Street operates at similar overall levels of service, while the intersection of 126th Street/GCP Ramp at 34 Avenue operates at overall marginally unacceptable LOS D during all game-day peak hours. The only individual movement on 34th Avenue that operates at unacceptable levels of service is westbound 34th Avenue approaching 126th Street which operates at marginally unacceptable LOS D during all non-game peak hours and at LOS E during the Saturday pre-game peak hour.

ASTORIA BOULEVARD

Similar to Northern Boulevard, the prevailing weekday AM traffic on Astoria Boulevard is in the westbound direction, and reversed in the weekday PM. Through the neighborhood of North Corona on the west side of the study area on a typical non-game day, eastbound Astoria Boulevard carries approximately 850 vph during the AM peak hour, which increases to approximately 2,225 vph during the PM peak hour. Conversely, the westbound direction carries approximately 1,925 vph during the AM peak hour, which decreases to approximately 850 vph during the PM peak hour. The weekday midday and Saturday midday traffic volumes are in the range of 925–1,000 vph eastbound and 650–750 westbound. Weeknight pre-game peak hour volumes on Astoria Boulevard are approximately 2,650 vph eastbound and 800 vph westbound. Weekend pre- and post-game peak hour volumes range from approximately 825–1,000 vph eastbound and 700–750 vph westbound. The analyzed intersection at 108th Street operates at overall LOS B or C during all analysis periods.

WEST PARK LOOP/STADIUM ROAD

West Park Loop/Stadium Road carries low to moderate volumes during non-game conditions, with approximately 50–350 vph per direction during weekday and Saturday non-game peak hours. The roadway experiences a substantial increase in traffic during game conditions due to access from the Grand Central Parkway westbound ramps. Game traffic uses West Park Loop/Stadium Road to access CitiField parking lots. Weekday and weekend pre-game arrival volumes are approximately 150–650 vph per direction. A large portion of post-game traffic travels westbound along West Park Loop/Stadium Road—from the north exits of the CitiField lots at Boat Basin Road—toward the Grand Central Parkway on-ramp. Westbound volumes along this short segment are as high as 1,500 vph approaching the on-ramp toward the westbound Grand Central Parkway ramp (toward eastbound Northern Boulevard and the northbound Whitestone Expressway) during the weekend post-game departure peak hour, while eastbound volumes are much lower, approximately 100 vph.

The intersection of West Park Loop/Stadium Road at Boat Basin Road operates at overall acceptable LOS C during all the non-game peak hours. During post-game conditions, NYPD deploys an officer to control the intersection to give preference to the northbound approach (traffic exiting the CitiField parking lots). During this time, NYPD converts the two southbound receiving lanes into northbound exclusive left turn lanes, and uses cones to divert all southbound traffic to westbound Stadium Road (so all southbound traffic must turn right). This typically lasts for the first 60 minutes after a game after which the intersection reverts back to normal operations.

COLLEGE POINT BOULEVARD

Along the western boundary of Downtown Flushing between Sanford Avenue and Roosevelt Avenue, College Point Boulevard carries approximately 550–1,000 vph per direction during the non-game peak hours. Through Northern Boulevard, College Point Boulevard is traveled by approximately 550–750 vph in both the northbound and southbound directions, during the non-game peak hours. During weeknight and weekend pre-game conditions, College Point Boulevard between Sanford Avenue and Roosevelt Avenue is traveled by approximately 1,150–1,350 vph northbound and 900–1,100 vph southbound. Along the same section of College Point Boulevard during the weekend post-game peak hour, there are approximately 750–1,200 vph in the northbound direction and 900–1,000 vph in the southbound direction. Through Northern Boulevard, College Point Boulevard is traveled by approximately 650–750 vph northbound and 400–700 vph southbound, during the game-day peak hours.

Overall levels of service along College Point Boulevard are generally at acceptable LOS B or C except for the intersection of College Point Boulevard and Roosevelt Avenue which operates at marginally acceptable LOS D during the weekday non-game PM, and weekend pre-game and post-game peak hours, and operates at marginally unacceptable LOS D during the weekday pre-game peak hour. Specifically during pre-game conditions, the College Point Boulevard northbound left turn at Roosevelt Avenue is congested and operates at unacceptable LOS F, due to increased traffic toward CitiField. The College Point Boulevard northbound left turn also operates at unacceptable LOS D during the weekday PM non-game peak hour.

MAIN STREET

Main Street carries approximately 500–650 vph northbound and 350–800 vph southbound, during the non-game and game day peak hours. Between Kissena Boulevard and Northern

Boulevard, Main Street also supports up to nine bus lines, with volumes as high as approximately 90 buses per hour per direction near Roosevelt Avenue.

All intersections analyzed along Main Street operate at overall acceptable levels of service (marginally acceptable LOS D or better). In order to address traffic congestion at its intersection with Roosevelt Avenue caused by the volume of buses and potential conflicts between vehicles and pedestrians, in addition to generally high traffic volumes, Main Street approaches are restricted to through movements only. However, there are some critical movements along Main Street that operate at unacceptable levels of service. At the intersection with Main Street/41st Avenue, the northbound left turn movement onto 41st Street operates at unacceptable LOS D during the non-game Saturday midday peak hour, and the southbound left turn movement onto Kissena Boulevard operates at marginally unacceptable LOS D during the weekday PM non-game and Saturday pre-game peak hours. At the intersection of Main Street at Northern Boulevard, the northbound right turn movement onto Northern Boulevard operates at marginally unacceptable LOS D during the non-game weekday AM and Saturday midday peak hours and during the weekday pre-game peak hour. This movement also operates at unacceptable LOS E during the weekday PM non-game and Saturday pre-game peak hours.

UNION STREET

Northbound volumes on Union Street are lower between Sanford Avenue and 41st Avenue (approximately 75–225 vph) than between 41st Avenue and Northern Boulevard (approximately 300–500 vph). In the southbound direction, Union Street is traveled by approximately 400–875 vph between Northern Boulevard and the Municipal Parking Lot entrance just north of 39th Street. South of the parking lot, southbound volumes are 325–525 vph. At Sanford Avenue, a substantial amount of Union Street's southbound traffic turns either left or right onto Sanford Avenue, and southbound traffic volumes diminish to 175–275 vph south of Sanford Avenue. Union Street also carries bus traffic for a number of transit routes.

Overall levels of service at Union Street intersections operate at marginally acceptable LOS D or better during all non-game and game day peak hours. All individual movements along Union Street also operate at acceptable levels of service during all peak hours.

PARSONS BOULEVARD

Through eastern Downtown Flushing, Parsons Boulevard is traveled by approximately 250–400 vph northbound and 225–475 vph southbound, during all non-game and game day peak hours. Parsons Boulevard typically has acceptable overall levels of service at the intersections analyzed, except for Parsons Boulevard at Northern Boulevard which operates at overall marginally unacceptable LOS D during the Saturday midday non-game peak hour. The northbound left turn and southbound shared left-through-right movements operate at unacceptable LOS D or E during most peak hours. Other individual movements along Parsons Boulevard that operate at unacceptable levels of service during at least one peak hour include the northbound approach at Roosevelt Avenue (unacceptable LOS D during the weekday AM non-game peak hour) and the northbound approach at Sanford Avenue (unacceptable LOS D during the weekday AM and midday non-game peak hours).

108TH STREET

108th Street carries approximately 150–325 vph in the northbound direction and 50–450 vph in the southbound direction during the non-game and game day peak hours. Overall intersection levels of service at analyzed 108th Street intersections are acceptable LOS D or better; however,

several 108th Street movements at these intersections operate at unacceptable levels of service. This includes the northbound *de facto* left turn movement at Astoria Boulevard (LOS mid-D during the weekday AM non-game peak hour) and the northbound and southbound approaches at Northern Boulevard and at Roosevelt Avenue (unacceptable LOS mid-D or E on both approaches at both intersections during all peak hours).

PRINCE STREET

Prince Street volumes are approximately 175–350 vph per direction during non-game and game day peak hours with the majority of southbound traffic at Northern Boulevard turning onto the westbound Northern Boulevard viaduct during most peak hours. Northbound Prince Street at Northern Boulevard consistently operates at unacceptable LOS E or F during all analysis peak hours, while the southbound approach operates at marginally acceptable LOS D at all times except during the weekday AM non-game peak hour where it operates at unacceptable LOS D. Prince Street at Roosevelt Avenue operates at acceptable levels of service during all peak hours.

111TH STREET

During all analysis peak hours, 111th Street northbound approaching Roosevelt Avenue is traveled by approximately 175–325 vph. Northbound 111th Street, which is the only approach to Roosevelt Avenue, since the street is one-way, operates at marginally unacceptable LOS D or LOS E during the non-game peak hours and at unacceptable LOS E during game day analysis peak hours.

114TH STREET

Northbound volumes on 114th Street are approximately 175–300 vph during the non-game analysis peak hours. There is heavy northbound right turn traffic at Roosevelt Avenue, and all northbound traffic approaching 34th Avenue turns onto the Grand Central Parkway on-ramp since the roadway becomes one-way southbound between that intersection and the intersection at Northern Boulevard. Northbound 114th Street volumes entering the Grand Central Parkway range between 225–300 vph for non-game conditions. In the southbound direction, volumes along 114th Street vary greatly due to the Grand Central Parkway on-ramp. During the non-game peak hours, southbound traffic approaching 34th Avenue is approximately 450–675 vph, but downstream, approaching Roosevelt Avenue, volumes are 125–250 vph.

Pre-game volumes on 114th Street northbound are approximately 200–325 vph (similar to non-game), and southbound volumes approaching 34th Avenue range between 700–800 vph. Approaching Roosevelt Avenue, volumes are approximately 250–425 vph, which are higher than non-game conditions due to increased left turns toward CitiField.

Northbound and southbound 114th Street at Roosevelt Avenue operate at unacceptable LOS D or E during all analysis periods. The southbound 114th Street left turn movement at 34th Avenue operates at marginally unacceptable LOS D or unacceptable LOS E during all game day peak hours. At Northern Boulevard, southbound 114th operates at marginally unacceptable LOS D during all peak hours except for the weekday and Saturday midday non-game peak hours which operate at marginally acceptable LOS D.

126TH STREET

126th Street between Roosevelt Avenue and 34th Avenue carries approximately 190–300 vph in the northbound direction and 200–360 vph in the southbound direction during the non-game analysis peak hours. Pre-game volumes on 126th Street in the northbound direction are

approximately 300–575 vph and southbound volumes are approximately 600–880 vph. Post-game volumes on 126th Street in the northbound direction are approximately 380–540 vph and southbound volumes are approximately 450–580 vph. Overall levels of service along 126th Street at 36th Avenue and at 37th Avenue are generally at acceptable LOS A, B, or C.

PARKING

OFF-STREET PARKING

An inventory of public parking lots was conducted within the area generally bounded by College Point Boulevard to the east, West Park Loop/Stadium Road and the Grand Central Parkway to the west, Flushing Bay to the north, and Perimeter Road in Flushing Meadows-Corona Park to the south. This study area constitutes a region within approximately ¼ mile from the boundary of the project site and encompasses the various parking lots used by the Mets and game-day attendees.

As shown in **Tables 14-7** and **14-8**, an inventory was conducted along with hourly parking facility occupancy surveys during the periods of 7:00 AM–10:00 AM, 11:00 AM–2:00 PM, and 4:00 PM–7:00 PM on a typical weekday (Tuesday, May 22, 2012), and 11:00 AM–2:00 PM on Saturday without a Mets home game (Saturday, June 9, 2012). For periods with a Mets home game, parking surveys were conducted from 4:30 PM to 7:30 PM (Tuesday, May 29, 2012) for the weekday PM pre-game arrival period and from 2:00 PM to 5:00 PM and 6:00 PM to 9:00 PM (Saturday, June 2, 2012) for the weekend pre- and post-game periods (see **Tables 14-9** and **14-10**). Similar to the traffic volumes, game day parking occupancies were conservatively adjusted upward to reflect an 85th percentile attendance at CitiField based on the 2010 and 2011 seasons since game attendance during the parking and traffic data collection was relatively low. On-street parking utilization was not adjusted since most Mets game attendees park in off-street facilities.

TOTAL	3,823	23-21%	38-36%	51-47%	47-44%	33-31%	15-14%
Notes: ¹ Capacity includes the median between eastbound and westbound Northern Boulevard, both east and west of 126th Street. ² South Lot and Lot D is currently striped as 1,556 parking spaces, but the surface lot has a higher capacity due to optimization of parking spaces by parking attendants.							

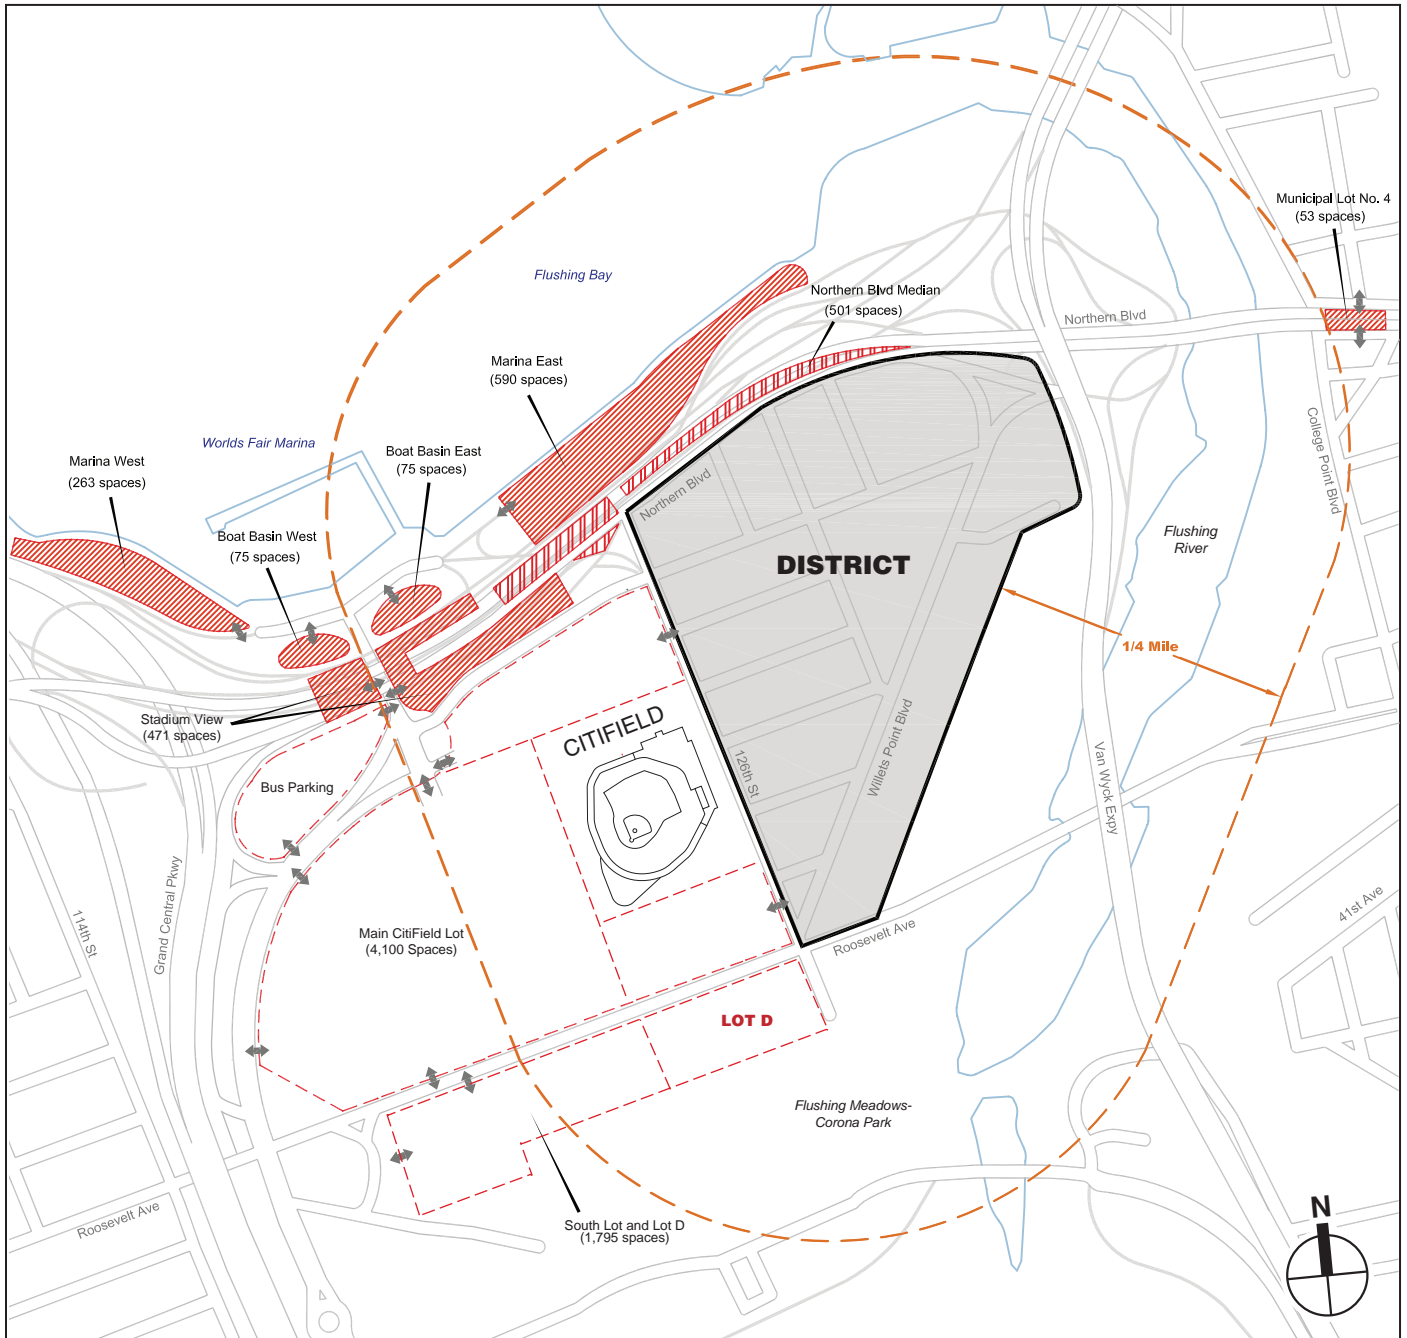

Overall, there is a mix of controlled and uncontrolled public parking lots as well as undesignated parking areas, including space on roadway shoulders and medians, which are typically used only during periods of high parking demand, such as during a Mets game (see **Figure 14-2**). The controlled lots include: the “main” CitiField lots (generally bounded by Roosevelt Avenue to the south, Shea Road to the north and west, and 126th Street to the east), which serve game and official stadium parking only on both game and non-game days; South Lot and Lot D¹, which serves as a pay park-and-ride lot for commuters on typical weekdays and weekends, and is a pay lot for CitiField during game periods; Marina East and Marina West, which are also pay lots for CitiField during game periods but are free and uncontrolled on typical weekdays and weekends; and Stadium View (Whitestone Lot) that flanks Boat Basin Road under the elevated expressway, which is also a pay lot for CitiField during game periods, but is free on non-game weekdays and weekends. Occupancy surveys of the main CitiField lots were not conducted since they serve only official CitiField and NYPD vehicles on typical weekdays and weekends, and official and attendee parking during game periods, so they would not regularly be publicly accessible.

The remaining group of lots and other off-street parking areas include: the Marina Boat Basin East and West lots; the Northern Boulevard dirt/pavement median both east and west of 126th Street, which have significantly higher usage during Mets game periods; and Municipal Lot No. 4, which is under the Northern Boulevard viaduct in Downtown Flushing. These parking lots are not part of CitiField’s pay parking facilities and, excluding Municipal Lot No. 4, are only partially used during typical weekdays and weekends when there is no Mets home game. Municipal Lot No. 4 is consistently utilized on both game and non-game-days.

Non-Game-Day Parking

As shown in **Table 14-7**, there are eight surveyed parking facilities open to public use on non-game days, containing approximately 3,823 spaces. During non-game days, all off-street parking facilities are less than 40 percent occupied throughout the day except for Municipal Lot Number 4 which is located at the western end of Downtown Flushing. This facility reaches capacity by 11 AM and remains at or near capacity until the 5-6 PM hour. CitiField’s South Lot/Lot D is by

¹ South Lot and Lot D currently operate as a single surface parking lot, with common entrance/exit locations.

- Special Willets Point District

0 1000 Feet
SCALE

far the largest inventoried parking facility in the area. This primary commuter (pay) lot near the District has a capacity of 1,795¹, does not exceed 32 percent occupancy during the weekdays without a Mets game, and drops to about 13 percent occupancy outside of the 8 AM to 6 PM period. Examining the other more distant lots during days without a Mets home game, the two Boat Basin lots and Marina West service the club and marina visitors; however, the larger nearby lots, such as Marina East and Stadium View, which are generally utilized only during game days, are at or near zero percent occupancy. Overall, during weekday non-game peak hours, off-street parking occupancies within the parking study area range between ~~10 and 23~~ 9 and 21 percent, resulting in a parking availability of ~~2,760 to 3,225~~ 3,020 to 3,475 spaces.

As shown in **Table 14-8**, the occupancy level ranges between ~~5~~ 4 and 7 percent between the hours of 11 AM and 6 PM on a typical Saturday without a Mets game. Therefore, there are approximately ~~3,335 to 3,400~~ 3,555 to 3,670 unoccupied spaces available within the off-street lots.

Game Day Parking

On game days, CitiField's South Lot and Lot D are used for game attendance parking only. During the weekday PM hours preceding a 7:10 PM-start Mets home game, parking occupancy in the surveyed lots is approximately 42 to 51 percent. As shown in **Table 14-9**, from 4:30 to 7:30 PM, South Lot and Lot D experiences a transition from commuter park-and-ride occupants to Mets game attendees and has a consistent occupancy of 37 percent until 6:30 PM, and has a subsequent increase to 44 percent by the start of the game. Other lots, such as Stadium View and Marina West, which are controlled for game traffic on game days only, increase in occupancy approaching the start of the game, but do not reach more than about 57 percent capacity. The available free parking on the Northern Boulevard median, which is frequently used for parking by Mets attendees, reaches 100 percent of its approximately 500-space capacity. The Marina East and Stadium View lots were nearly unutilized during the surveyed weekday Mets game. Overall, within the parking study area, off-street parking utilization ranges between ~~38 and 48~~ 36 and 45 percent during the 4:30 to 7:30 PM hours, resulting in a parking availability of approximately ~~1,860 to 2,225~~ 2,100 to 2,445 spaces.

Table 14-10 shows off-street parking inventories preceding and following a weekend Mets game with a 4:10 PM start. Only four of the off-street parking facilities are near or above 75 percent of capacity in the hours leading up to the game, and one of them, Municipal Lot 4, likely has few if any game attendees parking there. Boat Basin East is the only parking facility that reaches capacity during the weekend game day parking period, and it only has a capacity of 75 spaces. Overall, off-street parking utilization during weekend game days peaks at around 50 percent, leaving approximately 1,800 available spaces during that period, and demand tapers down after game time. By 8 PM, parking utilization in the study area is only at approximately one-third of the total capacity, and by 9 PM utilization drops to about ~~45~~ 14 percent.

ON-STREET PARKING

On-street parking inventories were conducted for a study area that generally covers the area within a ¼-mile radius of the Special Willets Point District and Willets West portions of the project site. This includes the area bounded by Northern Boulevard to the north, Willets Point Boulevard/Roosevelt Avenue to the south, College Point Boulevard to the east and 126th Street

¹ South Lot and Lot D is currently striped as 1,556 parking spaces, but the lot has a higher capacity due to optimization of parking spaces by parking attendants.

to the west. The inventory along College Point Boulevard extended further north to 32nd Avenue, which is slightly beyond the ¼-mile radius but still within walking distance.

Since much of the existing roadway network within the District is in general disrepair, there are few blocks with defined sidewalks, curbs, and designated on-street parking space, and much of the block lengths are comprised of garage entrances and extensions of the abutting land uses and are not adequately built and maintained for any type of on-street parking. The small number of regulated spaces within or adjacent to this area are generally located along the south curb of eastbound Northern Boulevard (between 126th Street and Willets Point Boulevard) and along 126th Street. The remaining block space that can accommodate on-street parking is not regulated, such as along partial sections of 126th Place, 127th Street, 127th Place, and Willets Point Boulevard, near Northern Boulevard, and along one block of 34th Avenue.

Overall, within the area surveyed, there are approximately 235–270 legal spaces available on-street (depending on time of day and prevailing regulations), including the unregulated blocks discussed above. Within the surveyed area, there are no legal spaces along Roosevelt Avenue, West Park Loop/Stadium Road, and 126th Street, with a mix of No Standing Anytime and No Parking Anytime, though there is frequent illegal parking along both sides of 126th Street.

As shown in **Table 14-11**, the number of parked vehicles counted for the AM, midday, and PM periods on a typical weekday (Tuesday, May 22, 2012) is near or above the total on-street capacity. This is primarily due to illegally parked vehicles along 126th Street between Roosevelt Avenue and Northern Boulevard. Some of the other surveyed blocks are also parked over capacity, with a number of trucks and other delivery vehicles double parked near the warehouses and industrial land uses in the area. Within the District, many of the limited, unregulated blocks that have curb space for parking are typically filled to or beyond capacity by double-parked vehicles and vehicles blocking driveway/garage entrances.

On-street parking usage is generally lower during non-game weekend periods. Based on the data collected during a Saturday non-game survey, most streets have parking utilization that is below overall parking capacity during surveyed hours; however, substantial illegal parking still occurs along 126th Street.

On days with a Mets game, on-street parking usage is generally lower during pre-game and post-game periods. The overall number of parked vehicles remains below capacity for the hours surveyed during a typical weekday (Tuesday, May 29, 2012) and Saturday with a Mets game (June 2, 2012). Overall, game fans opt to park in pay and free lots rather than along the limited curb space on-street where available. With additional parking demand, typically for a weekend game, a small number of game fans park on-street along the south side of Northern Boulevard adjacent to the District and the blocks of 127th Street and 127th Place just south of Northern Boulevard.

	Other										106	44	0

Notes: For weekdays and Saturday, the number of designated legal parking spaces increases from approximately 230 to 268 at 9:00 AM due to a 7:00–9:00 AM parking restriction along a section of College Point Boulevard. For weekdays only, the number of designated legal parking spaces decreases from approximately 268 to 246 at 4:00 PM due to a 4:00–7:00 PM parking restriction along a section of Northern Boulevard (The number of spaces include those within approximately ¼ mile of the District.)

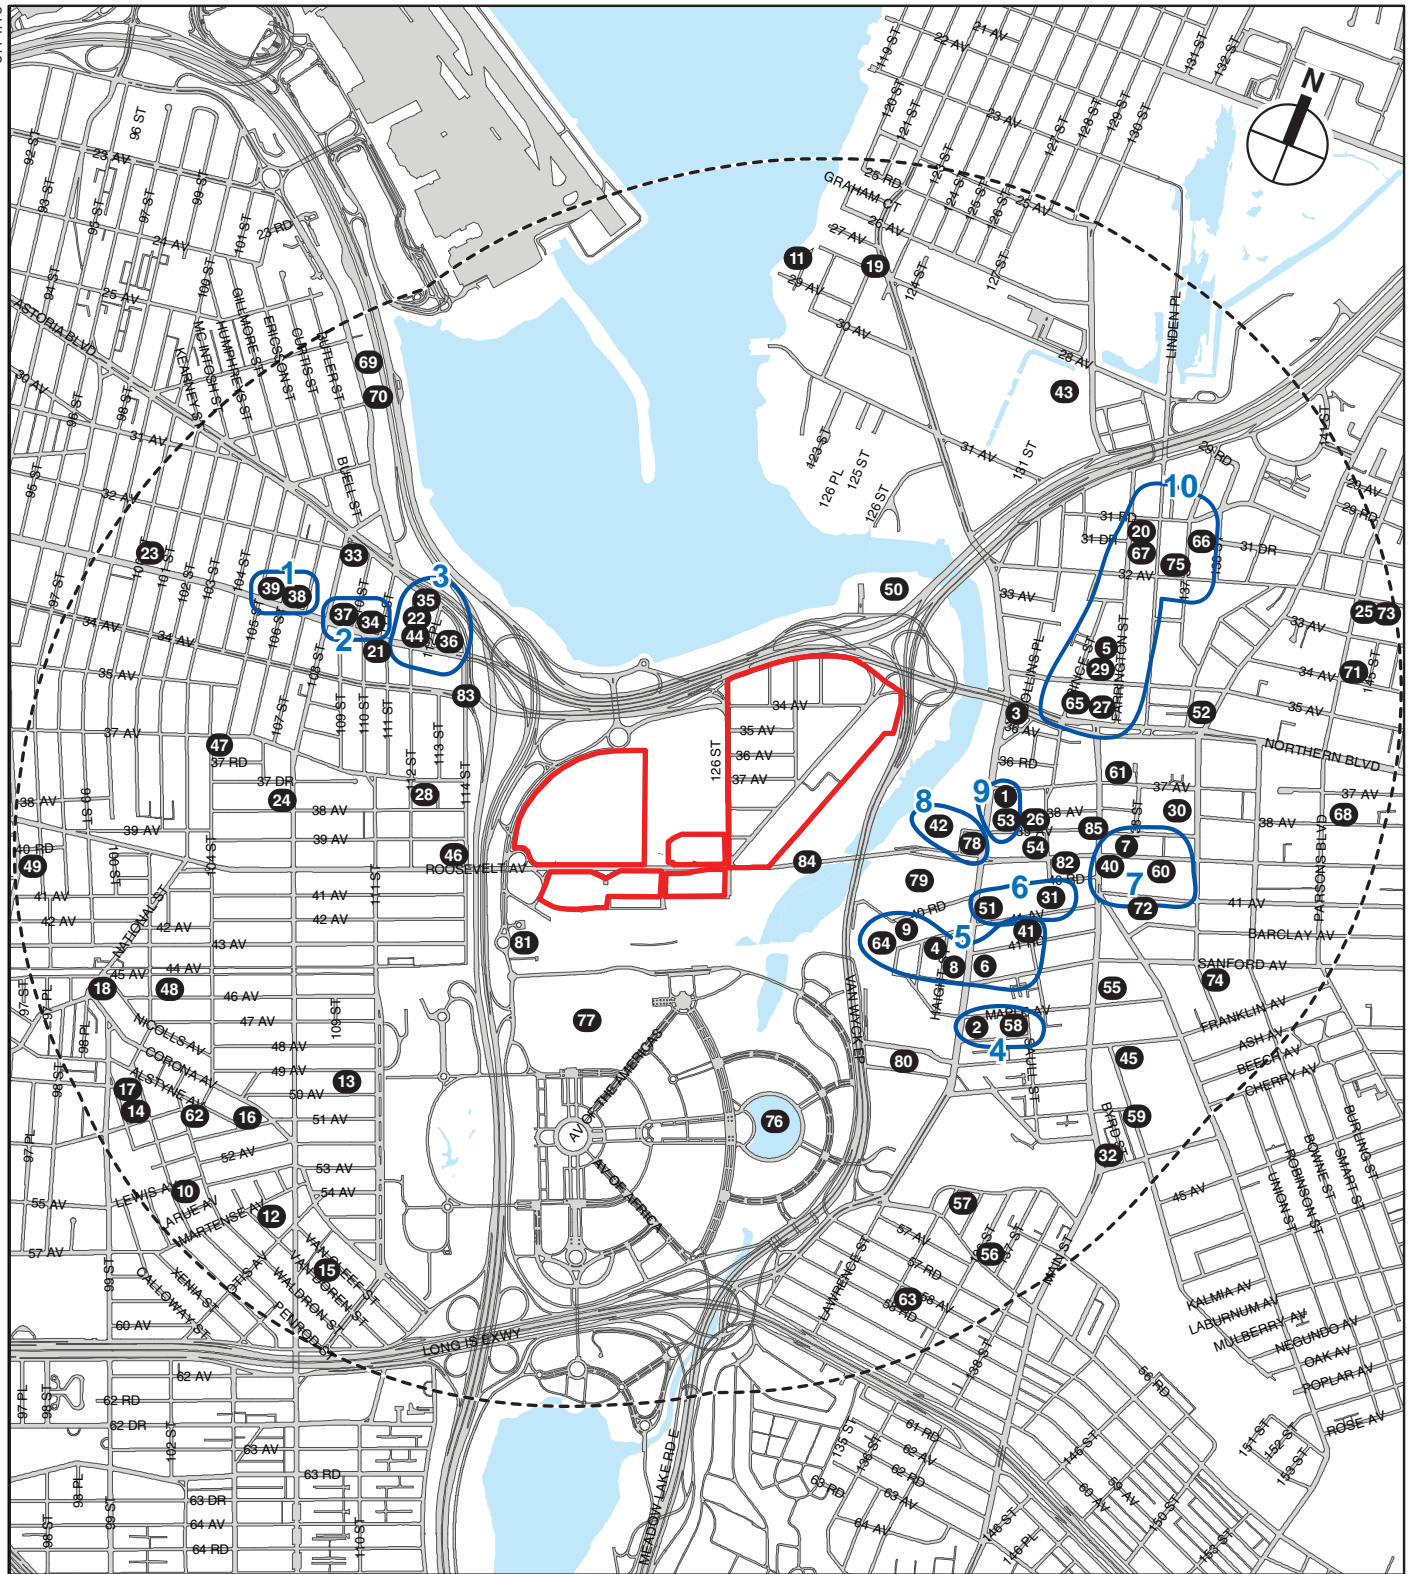

E. THE FUTURE WITHOUT THE PROPOSED PROJECT (TRAFFIC AND PARKING)

Future conditions without the proposed project (the No Action condition) are established in order to provide the baseline against which the impacts of the proposed project can be compared and to account for changes in traffic conditions between existing conditions and the future analysis years. Future year conditions were analyzed for each phase of the project: 2018 for Phase 1A; 2028 for Phase 1B; and 2032 for Phase 2. Future No Action traffic volumes for each phase were developed by applying a background traffic growth rate of 0.5 percent per year for the first five years and 0.25 percent per year for each additional year, as stated in the *CEQR Technical Manual*, and by adding trips expected to be generated by anticipated development projects that are expected to be operational by each respective Build ~~buildout~~ year.

NO ACTION BACKGROUND PROJECTS

Trip generation and specific traffic assignments for anticipated development projects were taken directly from their respective Environmental Impact Statements (EIS) or Environmental Assessment Statements (EAS) where such information was available. For projects where such information was not readily available, trip generation analyses were conducted to determine the volume of generated vehicle trips and these trips were assigned through study area intersections.

The 2018 No Action condition would include a large number of development projects within an area approximately up to and including one mile of the project site. (See **Table 14-12** for a complete list of No Action projects in the one-mile study area and corresponding **Figure 14-3**). One additional No Action project within the one-mile study area would be completed by 2019; however, this project would not generate significant new person or vehicle trips during peak analysis hours.

#76 – As detailed in Section Q.N, MLS trip-making is expected to be comparable to the Mets and occur on different days; therefore it is not analyzed as a separate No Action project.

#83 & #85 – Analysis revisions, if necessary, will be undertaken in coordination with DOT between Draft and Final SEIS.

After reviewing the development programs for each of the No Action projects, it was determined that background growth will address the increase in traffic and pedestrian levels for 33 of the small projects in the study area. These small projects are dispersed throughout the study area and are not clustered together on a single block. As a result, these sites would not add a noticeable amount of traffic to any single block and have been screened out; they are considered as part of the general background growth rate. Additionally, one No Action project would not generate significant new person or vehicle trips during peak analysis hours. Person and vehicle trips generated by the remaining 46 projects were then determined. Ten clusters were created, grouping nearby projects that would have similar assignment routes based on their location. The clusters and corresponding No Action project numbers are presented in **Table 14-13**.

Table 14-13
No Action Project Clusters

Cluster ID No.	No Action Projects (Refer to Figure 14-3)
1	38, 39
2	34, 37
3	22, 35, 36, 44
4	2, 58
5	4, 6, 8, 9, 41, 64
6	31, 51
7	7, 40, 60
8	42, 78
9	1, 53
10	5, 20, 27, 29, 65, 66, 67

Traffic assignments for the following projects were taken directly from their respective EIS/EAS, or latest available information from on-going studies: Sky View Parc; RKO Keith Plaza; Flushing Commons; and P.S. 287. For the College Point Boulevard Police Academy, most trips are expected to be generated during hours outside of this SEIS's analysis peak hours for the proposed project. A summary of all No Action project-generated vehicle trips is presented in **Table 14-14** for non-game-day peak hours and in **Table 14-15** for game-day peak hours.

As shown in **Table 14-14**, the expected magnitude of background development generated volumes added to the study area network for the non-game peak hours would be substantial, ranging from approximately 2,325 to 3,150 vehicle trips, with the lowest increment expected during the weekday AM peak hour and highest during the PM peak hour. As shown in **Table 14-15**, the expected magnitude of background development generated volumes added to the study area network for the game peak hours would also be substantial, ranging from approximately 1,950 to 2,375 vehicle trips.

PHASE 1A (2018) NO ACTION TRAFFIC CONDITIONS

Traffic volume increases on the study area's roadway network due to the cumulative effect of background projects are quantified and discussed below. The peak hour volumes reported below include the **Table 14-14** and **Table 14-15** traffic volumes assigned to the study area's networks, but do not include the general annual growth rate (0.5 percent per year for the first five years and 0.025 percent per year each additional year per CEQR guidelines) that has been separately applied to existing traffic volumes, which would add just under three percent more traffic to all streets. However, the annual increase is included in the 2018 No Action volume totals. Because of background growth and No Action developments, substantial increases in traffic volumes can be expected under the 2018 No Action condition, independent from those that the proposed project would add.

Table 14-14

Vehicle Trips from Background Development Projects—Non-Game Day

Project Name / Project Cluster	AM Peak		Midday Peak		PM Peak		Sat. Midday

The more substantial traffic increases between existing and No Action conditions would occur along the primary streets in the study area network, including Northern Boulevard, Roosevelt Avenue, Astoria Boulevard, and College Point Boulevard. Below is a detailed description of the projected traffic increases expected throughout the study area as a result of the No Action development projects.

Northern Boulevard volumes through Downtown Flushing between Parsons Boulevard and Union Street can be expected to increase by about 75 to 175 vph during the seven peak analysis hours. Westbound Northern Boulevard volumes between Main Street and Union Street would increase by about 60 to 115 vph, while eastbound Northern Boulevard volumes along the same section would increase by about 285 to 455 vph during the seven peak hours. At Prince Street and farther west, adjacent to the Special Willets Point District and Willets West, Northern Boulevard volumes can be expected to increase by approximately 75 to 670 vph per direction during all of the peak hours. Northern Boulevard volumes in the vicinity of 108th and 114th Street can be expected to increase by about 100 to 235 vph per direction during the seven peak analysis hours.

Traffic volumes on Roosevelt Avenue through Downtown Flushing between Parsons Boulevard and College Point Boulevard can be expected to increase by about 10 to 215 vph per direction during all of the peak analysis hours. Adjacent to the project site, Roosevelt Avenue volumes can be expected to increase by approximately 65 to 315 vph per direction during the seven peak analysis hours. Roosevelt Avenue volumes in the vicinity of 108th, 111th, and 114th Street can be expected to increase by about 55 to 145 vph per direction during all of the peak analysis hours.

Sanford Avenue volumes through Downtown Flushing between Parsons Boulevard and College Point Boulevard can be expected to increase by about 10 to 55 vph per direction during the seven peak analysis hours.

On the west side of the study area, in the vicinity of 114th Street, and also within the Special Willets Point District, volumes on 34th Avenue can be expected to increase by up to 10 vph during the weekday non-game AM and PM peak analysis hours.

Astoria Boulevard volumes in the vicinity of 108th and 114th Streets can be expected to increase by about 30 to 95 vph per direction during the peak analysis hours.

Volumes along West Park Loop/Stadium Road can be expected to increase by up to about 50 vph during the peak analysis hours.

College Point Boulevard volumes between Sanford Avenue and 32nd Avenue can be expected to increase by about 60 to 320 vph per direction during all the seven peak analysis hours except during the weekday non-game PM peak hour when volumes are expected to increase by about 90 to 505 vph per direction.

Main Street volumes from Kissena Boulevard to Roosevelt Avenue can be expected to increase by up to 40 vph during the seven peak analysis hours. Between Roosevelt Avenue and Northern Boulevard, northbound Main Street volumes would increase by up to 450 vph and southbound volumes would increase by up to 185 vph during the peak analysis hours.

Union Street volumes between Sanford Avenue and Northern Boulevard can be expected to increase by approximately 35 to 75 vph in the northbound direction and by approximately 10 to 235 vph in the southbound direction during the peak analysis hours.

Parsons Boulevard volumes between Northern Boulevard and Sanford Avenue can be expected to increase by up to 20 vph per direction during the peak analysis hours.

Traffic volumes along 108th Street in the vicinity of Astoria Boulevard and Northern Boulevard and at Roosevelt Avenue can be expected to increase by about 10 to 50 vph per direction during the seven peak analysis hours.

Prince Street volumes at Northern Boulevard and Roosevelt Avenue can be expected to increase by up to 30 vph per direction during the peak analysis hours.

Willetts Point Development

Traffic volumes along 111th and 114th Street in the vicinity of Roosevelt Avenue can be expected to increase by up to 5 vph per direction during the seven peak analysis hours. 114th Street volumes at 34th Avenue can be expected to increase by approximately 10 to 45 vph per direction during the peak analysis hours.

126th Street volumes between Northern Boulevard and Roosevelt Avenue can be expected to increase by approximately 35 to 95 vph per direction during the peak analysis hours.

Traffic volumes along westbound World's Fair Marina at Stadium Road can be expected to increase by up to 10 vph during the peak analysis hours.

Based on these projected traffic volume changes, 2018 No Action traffic levels of service were determined for the 31 No Action analysis locations within the study area. **Tables 14-16 and 14-17** show comparisons of overall intersection and individual movement levels of service, respectively, for existing and 2018 No Action conditions for non-game-day peak hours, and **Tables 14-18 and 14-19** show the comparisons for the game-day peak hours. It is clear, in comparing overall intersection levels of service and individual traffic movement levels of service, that considerably more locations would operate at LOS E or F under the 2018 No Action condition than in existing conditions due to the substantial additional volumes generated by the expected background developments superimposed on top of a background growth rate of 2.8 percent.

Table 14-16

**Overall Intersection Level of Service Summary Comparison
Existing vs. Phase 1A (2018) No Action Conditions—Non-Game Day**

Signalized Intersections	Existing Conditions				Phase 1A (2018) No Action Conditions

No. of Lane Groups at LOS F	3	0	0	0	17 <u>18</u>	17	22	20
Note: ¹ Under Phase 1A (2018) No Action conditions, all but one unsignalized lane group (northbound left turn movement of Boat Basin Road at World's Fair Marina during the weekday AM non-game peak hour) would operate at overall LOS A, B or C.								

Table 14-18
Overall Intersection Level of Service Summary Comparison
Existing vs. Phase 1A (2018) No Action Conditions—Game Day

Signalized Intersections	Existing Conditions			Phase 1A (2018) No Action Conditions		
	Weekday Pre-game	Saturday Pre-game	Saturday Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 Signalized Intersections ^[1]		
Overall Intersection LOS A/B/C	20	20	21	14 <u>10</u>	13	10
Overall Intersection LOS D	6	6	5	7 <u>8</u>	4	5
Overall Intersection LOS E	0	0	0	6	5	8
Overall Intersection LOS F	0	0	0	2	4	3
Notes: ¹ Under Phase 1A (2018) No Action conditions during game day peak hours, none of the five <u>eight</u> unsignalized intersections would operate at overall LOS E or F (all five <u>eight</u> would operate at overall LOS D or better) during the weekday pre-game peak hour; one intersection would operate at overall LOS E during the Saturday pre-game peak hour; and two intersections would operate at overall LOS E and one intersection would operate at LOS F during the Saturday post-game peak hour.						

Table 14-19
Traffic Lane Group Level of Service Summary Comparison
Existing vs. Phase 1A (2018) No Action Conditions—Game Day

Signalized Lane Groups	Existing Conditions			Phase 1A (2018) No Action Conditions		
	Weekday Pre-game	Saturday Pre-game	Saturday Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 Signalized Intersections ^[1]		
No. of Lane Groups at LOS A/B/C	76	90	89	61 <u>60</u>	72 <u>73</u>	72 <u>73</u>
No. of Lane Groups at LOS D	37	21	25	37 <u>40</u>	25	20 <u>21</u>
No. of Lane Groups at LOS E	15	16	15	11 <u>10</u>	8	9 <u>8</u>
No. of Lane Groups at LOS F	1	2	1	21	25	29
Notes: ¹ Under Phase 1A (2018) No Action conditions during game day peak hours, eight <u>13</u> of about 42 <u>17</u> unsignalized lane groups operate at LOS A, B, C or D during all peak hours. Four movements would operate at LOS E or F during at least one peak hour including: northbound left turns from Boat Basin Road onto World's Fair Marina (LOS E during weekday pregame and Saturday pregame peak hours and LOS F during the Saturday post game peak hour); the eastbound left-through movement on Stadium Road at Boat Basin Road (LOS F during Saturday pre- and post-game peak hours); westbound CitiField Entrance 9 at Boat Basin Road (LOS F during the Saturday post-game peak hour); and eastbound left turns from the GCP off-ramp onto Stadium Road (LOS E during the Saturday post-game peak hour).						

The summary overview of the Phase 1A (2018) No Action condition without a Mets game indicates that:

- In the weekday AM peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to eight under the Phase 1A No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 13 to 32 31.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to five, while the number of traffic lane groups at LOS E or F would increase from eight to 26.
- In the weekday PM peak hour, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to six under Phase

1A No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 13 to ~~34~~ 33.

- In the Saturday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to eight, while the number of lane groups at LOS E or F would increase from 11 to ~~33~~ 32.
- Most of the projected LOS E or F intersections would be located in Downtown Flushing.

The summary overview of the Phase 1A No Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to eight under the Phase 1A No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 16 to ~~32~~ 31.
- In the Saturday afternoon pre-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to nine under the Phase 1A No Action condition. The number of lane groups projected to operate at LOS E or F would increase from 18 to 33. The unsignalized intersection of Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS E.
- In the Saturday PM post-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to 11 under the Phase 1A No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 16 to ~~38~~ 37. The unsignalized intersections of Boat Basin Road at World's Fair Marina and Grand Central Parkway Ramp at West Park Loop/Stadium Road would operate at LOS E, and the unsignalized intersection of Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS F.

PHASE 1A (2018) NO ACTION PARKING CONDITIONS

Based on a background traffic growth rate of 2.8 percent to 2018, demand for off-street parking facilities and on-street parking in the area during the Phase 1A No Action condition can generally be expected to increase by the same rate. The maximum occupancy level for parking facilities on non-game days would increase by about one percent or less of total capacity in 2018 from the existing occupancy level range of 9 to 21 percent on a typical weekday without a Mets game. One facility, Municipal Lot 4, would reach capacity during the 4-5 PM hour under the Phase 1A No Action condition as compared to 98 percent occupancy under existing conditions. On a typical Saturday without a Mets game, the maximum occupancy level for parking facilities would increase by about one percent or less of total capacity in 2018 from the existing occupancy level range of 4 to 7 percent.

On a typical weeknight with a Mets game, the maximum occupancy which occurs between 6:30-7:30 PM would peak at about 46 percent in 2018 (excluding the main CitiField lots), compared to approximately 45 percent under existing conditions. On a typical weekend game day, the maximum occupancy (peaking at 4-5 PM) would increase by two percent, from 47 to 49 percent in 2018. This off-street demand projection for a weekend game day is a conservative assumption since it includes increases in Mets fan parking, which are not really subject to annual background increases.

Because the existing on-street parking occupancy is at or exceeds the legal capacity during most of the AM, midday, and PM periods (non-game and pre-game), and Saturday midday periods, the on-street parking utilization is assumed to continue to peak near or above 100 percent after increasing the existing on-street parking demand by the 2.8 percent background growth rate. On weekends

with a Mets game, total on-street parking occupancy would reach capacity during the 2-3 PM hour of the pre-game period during the Phase 1A 2018 No Action condition as compared to 98 percent under existing conditions. During the rest of the pre-game period (3-5 PM) on-street occupancies would increase slightly from a range of 83 to 87 percent overall under existing conditions to 85 to 89 percent in 2018. During the post-game period on-street parking occupancies would increase by about one percent from the existing usage range of 51 to 65 percent.

PHASE 1B (2028) NO ACTION TRAFFIC CONDITIONS

No additional No Action projects were identified beyond those projected for 2018 (detailed above); therefore, the peak hour volumes for the Phase 1B (2028) No Action condition consist of the same No Action project increments as Phase 1A plus the annual background growth for 16 years (2012 to 2028) which amounts to almost 5.5 percent. The increase in traffic volumes between Phase 1A (2018) and Phase 1B (2028) is relatively minor since background growth between the two phases is only about 2.5 percent overall and, as mentioned, both No Action years include the same No Action project vehicle trip increments.

Traffic volumes maps for Phase 1B are and detailed levels of service results are provided at the end of this chapter. Level of service summaries are provided in **Tables 14-20 to 14-23** and described in detail below.

Table 14-20

**Overall Intersection Level of Service Summary Comparison
Existing vs. Phase 1B (2018) No Action Conditions—Non-Game Day**

Signalized Intersections	Existing Conditions				Phase 1B (2028) No Action Conditions			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				26 Signalized Intersections ^[1]			
Overall Intersection LOS A/B/C	22	23	22	22	11	15	42 <u>11</u>	14
Overall Intersection LOS D	4	3	4	4	7	5	5 <u>7</u>	3
Overall Intersection LOS E	0	0	0	0	8 <u>7</u>	2	7 <u>6</u>	6
Overall Intersection LOS F	0	0	0	0	0 <u>1</u>	4	2	3

Notes: ¹ Under Phase 1B (2028) No Action conditions, all five eight unsignalized intersections would operate at overall LOS A, B or C.

Table 14-21

Overall Intersection LOS D	6	6	5	7 <u>8</u>	2	3
Overall Intersection LOS E	0	0	0	5	7	6
Overall Intersection LOS F	0	0	0	3	4	7
Note: ¹ Under Phase 1B (2028) No Action conditions during game day peak hours, none of the five <u>eight</u> unsignalized intersections would operate at overall LOS E or F (all five <u>eight</u> would operate at overall LOS D or better) during the weekday pre-game peak hour; one intersection would operate at overall LOS F during the Saturday pre-game peak hour; and one intersection would operate at overall LOS E and two intersections would operate at LOS F during the Saturday post-game peak hour.						

Table 14-23

Traffic Lane Group Level of Service Summary Comparison
Existing vs. Phase 1B (2028) No Action Conditions—Game Day

Signalized Lane Groups	Existing Conditions			Phase 1B (2028) No Action Conditions		
	Weekday Pre-game	Saturday Pre-game	Saturday Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 Signalized Intersections ⁽¹⁾		
No. of Lane Groups at LOS A/B/C	76	90	89	59	68 <u>70</u>	69 <u>70</u>
No. of Lane Groups at LOS D	37	21	25	34 <u>36</u>	27 <u>28</u>	24 <u>27</u>
No. of Lane Groups at LOS E	15	16	15	16 <u>17</u>	7	9 <u>8</u>
No. of Lane Groups at LOS F	1	2	1	21	28	29
Note: ¹ Under Phase 1B (2028) No Action conditions during game day peak hours, seven <u>12</u> of about 42 <u>17</u> unsignalized lane groups operate at LOS A, B, C or D during all peak hours. Five movements would operate at LOS E or F during at least one peak hour including: northbound left turns from Boat Basin Road onto World's Fair Marina (LOS E during the Saturday pregame peak hour and LOS F during the weekday pregame and Saturday post game peak hours); the eastbound left-through movement of Stadium Road at Boat Basin Road (LOS F during Saturday pre- and post-game peak hours); the eastbound through-right movement of Stadium Road at Boat Basin Road (LOS E during the Saturday pre-game peak hour); westbound CitiField Entrance 9 at Boat Basin Road (LOS F during the Saturday post-game peak hour); and eastbound left turns from the GCP off-ramp onto Stadium Road (LOS F during the Saturday post-game peak hour).						

The summary overview of the Phase 1B (2028) No Action condition without a Mets game indicates that:

- In the weekday AM peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to eight under the Phase 1B No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 13 to 33.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to six, while the number of traffic lane groups at LOS E or F would increase from eight to 27.
- In the weekday PM peak hour, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to ~~nine~~ eight under Phase 1B No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 13 to ~~35~~ 36.

- In the Saturday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to nine, while the number of lane groups at LOS E or F would increase from 11 to ~~37~~ 36.
- Most of the projected LOS E or F intersections would be located in Downtown Flushing.

The summary overview of the Phase 1B No Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to eight under the Phase 1B No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 16 to ~~37~~ 38.
- In the Saturday afternoon pre-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to 11 under the Phase 1B No Action condition. The number of lane groups projected to operate at LOS E or F would increase from 18 to 35. The unsignalized intersection of Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS F.
- In the Saturday PM post-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to 13 under the Phase 1A No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 16 to ~~38~~ 37. The unsignalized intersection of Grand Central Parkway Ramp at West Park Loop/Stadium Road would operate at LOS E, and the unsignalized intersections of Boat Basin Road at World's Fair Marina and Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS F.

PHASE 1B (2028) NO ACTION PARKING CONDITIONS

Based on a background traffic growth rate of almost 5.5 percent to 2028, demand for off-street parking facilities and on-street parking in the area during the Phase 1B No Action condition can generally be expected to increase by the same rate. The maximum occupancy level for parking facilities on non-game days would increase by about one percent or less of total capacity in 2028 from the existing occupancy level range of 9 to 21 percent on a typical weekday without a Mets game. One facility, Municipal Lot 4, would reach full capacity during the 4-5 PM hour under the Phase 1B No Action condition as compared to 98 percent occupancy under existing conditions. On a typical Saturday without a Mets game, the maximum occupancy level for parking facilities would also increase by about one percent or less of total capacity in 2028 from the existing occupancy level range of 4 to 7 percent.

On a typical weeknight with a Mets game, the maximum occupancy which occurs between 6:30-7:30 PM would peak at about 48 percent in 2028 (excluding the main CitiField lots), compared to approximately 45 percent under existing conditions. On a typical weekend game day, the maximum occupancy (peaking at 4-5 PM) would increase by approximately three percent (from 47 percent to 50 percent) in 2028 as compared to existing conditions. This off-street demand projection for a weekend game day is a conservative assumption since it includes increases in Mets fan parking, which are not really subject to annual background increases.

Because the existing on-street parking occupancy is near or exceeds the legal capacity during most of the AM, midday, and PM periods (non-game and pre-game), and Saturday midday periods, the on-street parking utilization is assumed to continue to peak near or above 100 percent after increasing the existing on-street parking demand by the background growth rate. On weekends with a Mets game, total on-street parking occupancy would reach capacity during

the 2-3 PM hour of the pre-game period during the Phase 1B (2028) No Action condition as compared to 98 percent under existing conditions. During the rest of the pre-game period (3-5 PM), on-street occupancies would increase slightly from a range of 83 to 87 percent overall under existing conditions to 87 to 92 percent in 2028. During the post-game period, on-street parking occupancies would increase by three percent, from a range of 51 to 65 percent under existing conditions to a range of 54 to 68 percent in the Phase 1B (2028) No Action condition.

PHASE 2 (2032) NO ACTION TRAFFIC CONDITIONS

As mentioned previously, no additional No Action projects were identified beyond those projected for 2018 (detailed above in the Phase 1A No Action discussion); therefore, the peak hour volumes for the Phase 2 (2032) No Action condition consist of the same No Action project increments as Phase 1A plus the annual background growth for 20 years (2012 to 2032) which amounts to almost 6.5 percent. As with Phase 1B, the increase in traffic volumes under Phase 2 is relatively minor as compared to Phase 1A since background growth between Phase 1A (2018) and Phase 2 (2032) is only about 3.5 percent overall. Traffic volume maps for the Phase 2 No Action condition and detailed levels of service results are provided in traffic appendices at the end of this chapter. Level of service summaries are provided in **Tables 14-24 to 14-27** and discussed below.

Table 14-24
Overall Intersection Level of Service Summary Comparison
Existing vs. Phase 2 (2032) No Action Conditions—Non-Game Day

Signalized Intersections	Existing Conditions				Phase 2 (2032) No Action Conditions			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				26 Signalized Intersections ^[1]			
Overall Intersection LOS A/B/C	22	23	22	22	11	15	42 <u>11</u>	14
Overall Intersection LOS D	4	3	4	4	7	4	5 <u>7</u>	2
Overall Intersection LOS E	0	0	0	0	7	3	7 <u>6</u>	7
Overall Intersection LOS F	0	0	0	0	1	4	2	3
Note: ¹ Under Phase 2 (2032) No Action conditions, all five <u>eight</u> unsignalized intersections would operate at overall LOS A, B or C.								

Table 14-25
Traffic Lane Group Level of Service Summary Comparison
Existing vs. Phase 2 (2032) No Action Conditions—Non-Game Day

Signalized Movements	Existing Conditions				Phase 2 (2032) No Action Conditions			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				26 Signalized Intersections ^[1]			
No. of Lane Groups at LOS A/B/C	80	97	86	88	56	72 <u>74</u>	57 <u>58</u>	69 <u>70</u>
No. of Lane Groups at LOS D	34	24	30	30	38 <u>41</u>	30 <u>31</u>	38 <u>39</u>	24 <u>27</u>
No. of Lane Groups at LOS E	10	8	13	11	13	40 <u>9</u>	9 <u>11</u>	46 <u>15</u>
No. of Lane Groups at LOS F	3	0	0	0	22	48 <u>19</u>	25 <u>24</u>	21
Note: ¹ Under Phase 2 (2032) No Action conditions, all but one unsignalized lane group (northbound left turn movement of Boat Basin Road at World's Fair Marina during the weekday AM non-game peak hour) would operate at overall LOS A, B or C.								

Table 14-26

Overall Intersection Level of Service Summary Comparison
Existing vs. Phase 2 (2032) No Action Conditions—Game Day

Signalized Intersections	Existing Conditions			Phase 2 (2032) No Action Conditions		
	Weekday Pre-game	Saturday Pre-game	Saturday Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 Signalized Intersections ^[1]		
Overall Intersection LOS A/B/C	20	20	21	8 <u>7</u>	12	10
Overall Intersection LOS D	6	6	5	10 <u>11</u>	2	2
Overall Intersection LOS E	0	0	0	5 <u>4</u>	7	7
Overall Intersection LOS F	0	0	0	3 <u>4</u>	5	7
Note: ¹ Under Phase 2 (2032) No Action conditions during game day peak hours, none of the five eight unsignalized intersections would operate at overall LOS E or F (all five eight would operate at overall LOS D or better) during the weekday pre-game peak hour; one intersection would operate at overall LOS F during the Saturday pre-game peak hour; and one intersection would operate at overall LOS E and two intersections would operate at LOS F during the Saturday post-game peak hour.						

Table 14-27

Traffic Lane Group Level of Service Summary Comparison
Existing vs. Phase 2 (2032) No Action Conditions—Game Day

Signalized Lane Groups	Existing Conditions			Phase 2 (2032) No Action Conditions		
	Weekday Pre-game	Saturday Pre-game	Saturday Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 Signalized Intersections ^[1]		
No. of Lane Groups at LOS A/B/C	76	90	89	57	64 <u>66</u>	69 <u>70</u>
No. of Lane Groups at LOS D	37	21	25	34 <u>36</u>	28 <u>29</u>	23 <u>26</u>
No. of Lane Groups at LOS E	15	16	15	16 <u>17</u>	7	6 <u>5</u>
No. of Lane Groups at LOS F	1	2	1	23	31	32
Note: ¹ Under Phase 2 (2032) No Action conditions during game day peak hours, seven 12 of about 42 17 unsignalized lane groups operate at LOS A, B, C or D during all peak hours. Five movements would operate at LOS E or F during at least one peak hour including: northbound left turns from Boat Basin Road onto World's Fair Marina (LOS E during the Saturday pregame peak hour and LOS F during the weekday pregame and Saturday post-game peak hours; the eastbound left-through movement of Stadium Road at Boat Basin Road (LOS F during Saturday pre- and post-game peak hours); the eastbound through-right movement of Stadium Road at Boat Basin Road (LOS E during the Saturday pre-game peak hour); westbound CitiField Entrance 9 at Boat Basin Road (LOS F during the Saturday post-game peak hour); and eastbound left turns from the GCP off-ramp onto Stadium Road (LOS E during the weekday and Saturday pre-game peak hours, and LOS F during the Saturday post-game peak hour).						

The summary overview of the Phase 2 (2032) No Action condition without a Mets game indicates that:

- In the weekday AM peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to eight under the Phase 2 No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 13 to 35.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to seven, while the number of traffic lane groups at LOS E or F would increase from eight to 28.
- In the weekday PM peak hour, the number of locations that are projected to operate at overall LOS E or F would increase from none under existing conditions to ~~nine~~ eight under

Phase 2 No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 13 to ~~34~~ 35.

- In the Saturday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from zero to ten, while the number of lane groups at LOS E or F would increase from 11 to ~~37~~ 36.
- Most of the projected LOS E or F intersections would be located in Downtown Flushing.

The summary overview of the Phase 2 No Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, of the 26 signalized intersections analyzed, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to eight under the Phase 2 No Action condition. The number of traffic lane groups projected to operate at LOS E or F would increase from 16 to ~~39~~ 40.
- In the Saturday midday pre-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to 12 under the Phase 2 No Action condition. The number of lane groups projected to operate at LOS E or F would increase from 18 to 38. The unsignalized intersection of Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS F.
- In the Saturday PM post-game peak hour, the number of locations that are projected to operate at LOS E or F would increase from zero under existing conditions to 14 under the Phase 2 No Action conditions. The number of lane groups projected to operate at LOS E or F would increase from 16 to ~~38~~ 37. The unsignalized intersection of Grand Central Parkway Ramp at West Park Loop/Stadium Road would operate at LOS E, and the unsignalized intersections of Boat Basin Road at World's Fair Marina and Boat Basin Road at Stadium Road/CitiField Entrance 8 would operate at LOS F.

PHASE 2 (2032) NO ACTION PARKING CONDITIONS

Based on a background traffic growth rate of almost 6.5 percent to 2032, demand for off-street parking facilities and on-street parking in the area during the Phase 2 No Action condition can generally be expected to increase by the same rate. The maximum occupancy level for parking facilities on non-game days would increase by two percent or less of total capacity in 2032 from the existing occupancy level range of 9 to 21 percent on a typical weekday without a Mets game. One facility, Municipal Lot 4, would reach full capacity during the 4-5 PM hour under the Phase 2 No Action condition as compared to 98 percent occupancy under existing conditions. On a typical Saturday without a Mets game, the maximum occupancy level for parking facilities would increase by about one percent or less of total capacity in 2032 from the existing occupancy level range of 4 to 7 percent.

On a typical weeknight with a Mets game, the maximum occupancy which occurs between 6:30-7:30 PM would peak at about 48 percent in 2032 (excluding the main CitiField lots), compared to approximately 45 percent under existing conditions. On a typical weekend game day, the maximum occupancy (peaking at 4-5 PM) would increase by approximately four percent (from 47 percent to 51 percent) in 2032 as compared to existing conditions. This off-street demand projection for a weekend game day is a conservative assumption since it includes increases in Mets fan parking, which are not really subject to annual background increases.

Because the existing on-street parking occupancy is at or exceeds the legal capacity during most of the AM, midday, and PM periods (non-game and pre-game), and Saturday midday periods, the on-street parking utilization is assumed to continue to peak near or above 100 percent after

increasing the existing on-street parking demand by the background growth rate. On weekends with a Mets game, total on-street parking occupancy would exceed capacity during the 2-3 PM hour of the pre-game period during the Phase 2 (2032) No Action condition as compared to 98 percent under existing conditions. During the rest of the pre-game period (3-5 PM) on-street occupancies would increase by approximately five percent from a range of 83 to 87 percent overall under existing conditions to 88 to 93 percent in 2032. During the post-game period, on-street parking occupancies would increase by approximately three percent, from a range of 51 to 65 percent under existing conditions to a range of 54 to 69 percent in the Phase 2 (2032) No Action condition.

F. PROBABLE IMPACTS OF THE PROPOSED PROJECT (TRAFFIC AND PARKING)

The proposed project would redevelop the Willets Point/CitiField area with a mix of uses over a 18-year period. As mentioned, this development would occur in three continuous phases. Therefore, three separate Build years were analyzed corresponding to each phase: Phase 1A (2018); Phase 1B (2028); and Phase 2 (2032). Proposed development under each phase is as follows:

- By 2018 (Phase 1A), the development of an approximately 23-acre portion of the Special Willets Point District (the “District”) with a 200-room hotel, approximately 30,000 square feet of retail space, an approximately 2,825-space surface parking area/off-season public recreation space, and the development of the parking field west of CitiField with “Willets West”—a retail and entertainment center of approximately 1.4 million square feet (1 million square feet of leaseable area) and a 2,900-space parking garage (including 2,500 spaces for the Willets West retail/entertainment center and 400 spaces as replacement parking to be used for the Mets); and the development of a structured parking facility on the westernmost CitiField surface parking lot south of Roosevelt Avenue (South Lot);
- By 2028 (Phase 1B), the replacement of the interim surface parking area/off-season recreation space (the parking spaces would be relocated to two new structured parking facilities on the CitiField surface parking lots south of Roosevelt Avenue [South Lot/Lot D]) and the creation of approximately 4.23 million square feet of residential, retail, office, hotel, public school, community facility, enclosed parking, and public open space uses within the District; and
- By 2032 (Phase 2), the full build-out of the Special Willets Point District substantially as anticipated in the 2008 FGEIS, and the development of retail, and office uses on portions of the CitiField leasehold north of Roosevelt Avenue (Lot B).

Table 14-28 identifies the development program analyzed for the full buildout of the proposed project, including development in the District and Willets West, as well as the potential future development of Lot B. The proposed program development for each of the interim phases is summarized in detail later in the chapter (**Tables 14-42** and **14-52**).

**Table 14-28
Full Buildout Development Program for Analysis**

Use		Size
Willels West ⁽¹⁾	Destination Retail	915,000 SF
	Movie Theater	4,000 Seats (80,000 SF) ⁽²⁾
Special Willels Point District	Residential	5,850 DU
	Destination Retail	657,000 SF
	Local Retail	593,000 SF
	Office	500,000 SF
	Convention Center	400,000 SF
	Hotel	700 Rooms
	Community Facility	150,000 SF
Lot B Development	Public School (K-8)	1,463 Seats
	Destination Retail	184,500 SF
Total	Office	280,000 SF
Total	Residential	5,850 DU
	Destination Retail	1,756,500 SF
	Movie Theater	4,000 Seats
	Local Retail	593,000 SF
	Office	780,000 SF
	Convention Center	400,000 SF
	Hotel	700 Rooms
	Community Facility	150,000 SF
	Public School (K-8)	1,463 Seats
Notes:		
(1) Willels West would contain approximately 1.4 million sf of development, including 400,000 sf of non-leasable common area. This ancillary space is not considered for trip generation purposes.		
(2) Willels Point Development Plan FGEIS (2008) assumption of 20 sf per seat.		
SF = square feet		
DU = dwelling unit		

TRIP GENERATION AND MODAL SPLIT

Travel demand estimates were prepared for each of the nine land use types. Trip generation estimates were developed in consultation with the New York City Department of Transportation (NYCDOT) and rely on other representative developments with similar land uses, area types, etc., for appropriate trip generation rates. To the extent possible, the travel demand assumptions previously used in the 2008 FGEIS were applied. The specific travel demand factors for the SEIS are shown in **Table 14-29** and **Table 14-30** and are described in detail below.

RESIDENTIAL

For the residential component, the weekday and Saturday person and delivery trip generation rates are from the 2012 *CEQR Technical Manual*.

For the SEIS, the latest U.S. Census American Community Survey (ACS) 2006-2010 journey-to-work data were used to develop the modal split for the weekday AM, midday, PM, and

evening peak hours based on data for the following census tracts in Queens County (based on 2010 U.S. Census tract boundaries): 381, 383.01, 383.02, 399, 401, 403, 415, 849, 853, 855, 857, 865, 869, and 871. These tracts covered approximately the same areas studied in the 2008 FGEIS with the 2000 Census data. Census Tracts 383.01 and 383.02, which encompass the project site, are large tracts with few residential units; therefore, the study area was expanded to include tracts in Corona and Flushing. These tracts have access and transit characteristics similar to the project site. The Saturday modal split was adjusted from the Census journey-to-work data to reflect anticipated higher auto and walk shares.

Auto occupancy rates from the journey-to-work data were used for all analysis peak hours. The vehicle occupancy for auto trips was applied to taxi trips.

For the weekday AM, midday, and PM peak hours, the temporal distributions are from the 2012 *CEQR Technical Manual* and the directional distributions are from the 2008 FGEIS. For the weekday evening peak hour, the temporal and directional distributions are from the 2008 FGEIS. For the Saturday non-game midday peak, the temporal and directional distributions are from the 2012 *CEQR Technical Manual* and 2008 FGEIS, respectively. The Saturday pre-game and post-game temporal and directional distributions are from the 2008 FGEIS.

The weekday AM, midday, and PM and Saturday non-game midday peak hour delivery trip temporal and directional distributions are from the 2012 *CEQR Technical Manual*. The weekday evening and the Saturday pre-game and post-game delivery trip temporal and directional distributions are from the 2008 FGEIS.

OFFICE

The trip generation analysis for the office component used daily trip generation rates reported in the 2012 *CEQR Technical Manual* for the weekday and Saturday trip generation. The weekday and Saturday delivery trip generation rates are also based on the 2012 *CEQR Technical Manual*.

Census 2000 (U.S. Department of Commerce Bureau of the Census, 2000) reverse journey-to-work data (for the Queens County census tracts 851, 853, 855, 857, 865, 867, 871, and 875, based on 2000 U.S. Census tract boundaries) were used to develop the modal split and vehicle occupancies for the AM, PM, evening, and Saturday peak hours. The weekday midday peak hour modal splits and vehicle occupancies are based on the 2008 FGEIS. As presented in the 2008 FGEIS, the vehicle occupancy for taxi trips was assumed to be the same as for auto trips. Both are from Census reverse journey-to-work data.

The weekday AM, midday, and PM and the Saturday non-game midday/afternoon peak hour temporal and directional distributions are from the 2012 *CEQR Technical Manual* and the 2008 FGEIS, respectively. The weekday evening and the Saturday pre-game and post-game temporal and directional distribution rates are from the 2008 FGEIS.

The weekday AM, midday, and PM and Saturday non-game midday/afternoon peak hour delivery trip temporal and directional distributions are from the 2012 *CEQR Technical Manual*. The weekday evening and the Saturday pre-game and post-game delivery trip temporal and directional distributions are from the 2008 FGEIS.

DESTINATION RETAIL

The weekday and Saturday person and delivery trip generation rates for the project's destination retail component are from the 2012 *CEQR Technical Manual*. The weekday AM, midday, and PM and the Saturday non-game midday/afternoon peak hour temporal and directional

distributions are from the 2012 *CEQR Technical Manual* and the 2008 FGEIS, respectively. The weekday evening and the Saturday pre-game and post-game temporal and directional distribution rates are from the 2008 FGEIS. Because it is expected that some of the retail trips will be made by the project's residents and workers en route to or from their homes or offices on the project site, some internalization of trip-making is expected.

The weekday and Saturday modal splits and vehicle occupancies for the destination retail component are from the 2008 FGEIS. The weekday AM, midday, and PM and Saturday non-game midday/afternoon peak hour delivery trip temporal and directional distributions are from the 2012 *CEQR Technical Manual*. The weekday evening and the Saturday pre-game and post-game delivery trip temporal and directional distributions are from the 2008 FGEIS.

LOCAL RETAIL

The weekday and Saturday daily trip generation and delivery vehicle trip generation rates for the project's local neighborhood retail component are from the 2012 *CEQR Technical Manual*. A 25 percent linked trip credit was applied to the local retail trip generation estimates. The modal splits and vehicle occupancies are from the 2008 FGEIS.

Weekday AM, midday, and PM and Saturday non-game midday peak hour person and delivery trip temporal and directional distributions are from the 2012 *CEQR Technical Manual* and the 2008 FGEIS, respectively. The weekday evening and the Saturday pre-game and post-game person and delivery trip temporal and directional distributions are from the 2008 FGEIS.

CONVENTION / EXPO FACILITY

The weekday and Saturday travel demand assumptions for the project's convention/expo facility component are all based on the 2008 FGEIS.

MOVIE THEATER

The weekday and Saturday person daily trip generation rates for the project's movie theater component were from rates presented in the 2012 *CEQR Technical Manual*. The modal splits and auto and taxi occupancy rates are from the 2008 FGEIS. The weekday AM, midday, and PM and Saturday non-game midday/afternoon peak hour person trip temporal distributions are from the 2012 *CEQR Technical Manual*. The weekday evening and the Saturday pre-game and post-game person trip temporal distributions are from the 2008 FGEIS. The weekday and Saturday directional distributions are from the 2008 FGEIS. Weekday and Saturday delivery trip generation rates and the temporal and directional distributions are from the 2008 FGEIS.

HOTEL

The weekday and Saturday daily trip generation rates are from the 2012 *CEQR Technical Manual*. The weekday AM, midday, and PM and the Saturday non-game midday/afternoon peak hour person trip temporal distributions are also from the 2012 *CEQR Technical Manual*. The weekday evening and Saturday pre-game and post-game person trip temporal distributions are from the 2008 FGEIS. The modal splits, vehicle occupancies, and directional distributions are from the 2008 FGEIS. The weekday and Saturday delivery trip generation rates and temporal and directional distributions are from the 2008 FGEIS.

COMMUNITY FACILITY

The weekday and Saturday travel demand assumptions for the project's community facility component are all based on the 2008 FGEIS. The modal split for the community facility use was

similarly adjusted like the FGEIS based on the latest 2006-2010 ACS journey-to-work data. The journey-to-work data were adjusted to reflect a larger percentage of walk trips and a lesser percentage of trips by other modes. This assumption is predicated on a majority of the community facility trips being made by the project's residents, same as in the FGEIS.

SCHOOL

The weekday and Saturday travel demand assumptions for the project's school component are all based on the 2008 FGEIS.

RECREATIONAL USES (PHASE 1A ONLY)

The weekday and Saturday trip generation rates for the non-game day/off-season recreational uses (which may include a driving range, miniature golf, batting cages, and basketball/volleyball courts among other activities for approximately six months of the year) were derived from factors presented in the *Trip Generation Manual, 8th Edition* (ITE, 2008) for Land Use 435, "Multipurpose Recreational Facility." The recreational uses are likely to have a similar patron draw as the destination retail component described above; therefore, the destination retail modal splits and vehicle occupancies were also assumed for this land use. Accordingly, with these uses' proximity to nearby hotel and retail uses, including the Willets West retail development, and synergy with recreational uses in the adjacent Flushing Corona Meadows Park, a 25 percent linked trip credit was assumed and applied to the trip generation estimates.

Because these recreational uses would only be available on non-game days at CitiField, they would not generate any trips during the weekday pre-game, Saturday pre-game, and Saturday post-game analysis peak hours. The weekday AM and PM and Saturday non-game temporal distributions are based on the ratio of the peak hour of generator trip rates as compared to the total daily trip rates presented in the *Trip Generation Manual, 8th Edition* (ITE, 2008) for Land Use 435, "Multipurpose Recreational Facility." The weekday midday temporal distribution was assumed to be the same as the weekday PM temporal distribution. The weekday and Saturday peak hour directional distributions are based on factors presented in the *Coney Island Rezoning Final Environmental Impact Statement* (2009) for the amusement park land use. The weekday and Saturday delivery trip generation rates and temporal distributions are based on the factors presented in the *Coney Island Rezoning FEIS* for the amusement park land use, converted from per 1,000 square feet to per acre.

These travel demand assumptions were used to calculate the number of person and vehicle trips expected to be generated by development component during each of the proposed project's buildout phases.

PROPOSED ROADWAY IMPROVEMENTS

Over the course of the buildout of the proposed project, there would be several changes to the roadway network within the District occurring in each of the three phases. The roadway changes that would occur in each phase of development are summarized as follows:

- By Phase 1A (2018), 36th, 37th, 38th and 39th Avenues would be closed within the District, and Willets Point Boulevard would be closed between 127th and 126th Streets. These closures would be made to accommodate CitiField parking (2,750 spaces) displaced by the proposed Willets West development and would be used as recreational space in the off-season. In the Willets West area, at its intersection with Boat Basin Road, the eastbound approach of Stadium Road would be reconstructed so that it no longer intersects Boat Basin Road as an unsignalized intersection at the CitiField main parking lot entrance (Entrance 8), and instead intersects Boat Basin Road with the rest of Stadium Road, just to the north.

Additionally, a primary entrance to the proposed Willets West development would be created at the intersection of the GCP Off-Ramp at West Park Loop Road/Stadium Road. The Willets West entrance would become the east leg of this intersection.

- Between Phase 1A (2018) and Phase 1B (2028), a new access ramp from the northbound Van Wyck Expressway would be constructed off of the existing Exit 13 ramp and would connect to the new street network within the District at its northeast corner. A new ramp to the southbound Van Wyck Expressway would connect the northeast corner of the District to the expressway mainline immediately south of the interchange with the Whitestone Expressway via a new connection with the existing westbound Northern Boulevard ramp to the southbound Van Wyck Expressway. The new ramps would provide inbound trip access to the District from the northbound Van Wyck Expressway and outbound trip access from the District to the southbound Van Wyck Expressway. They would also continue to provide access to the eastbound and westbound Grand Central Parkway via the existing ramp that connects to the southbound Whitestone Expressway which travels west along the northern edge of the District. Also, Willets Point Boulevard would be extended southwest to where it currently meets 38th Avenue and then west to intersect with 126th Street (along what is currently 38th Avenue). Additionally, two new east-west retail streets would be created in the District along 36th and 37th Avenues and would intersect 126th Street—one at the CitiField entrance center line, and one near CitiField's northern edge. A third retail street running north-south between 35th Avenue and the current 38th Avenue (Willets Point Boulevard extension in the proposed project), would intersect those connector streets. A short segment of another proposed new north-south street that would traverse the eastern border of the District (adjacent to the abutting MTA lot) would be created. This segment would span the distance of approximately one block, starting from just north of Roosevelt Avenue, and then turn west where it would intersect Willets Point Boulevard.
- Between Phase 1B (2028) and Phase 2 (2032), the District's new internal street network would be completed. The proposed north-south street along the eastern border of the District would be fully extended to the northern end of the District, and would generally run parallel to Willets Point Boulevard. Additional east-west streets would be added to service new development parcels. Additionally, 35th Avenue would be demapped and closed within the District to accommodate new development parcels in the northwest section of the District. It is anticipated that these parcels would be surrounded by new internal roadways as well. Additionally, a new intersection would be created along Roosevelt Avenue at the entrance to Lot B to accommodate proposed development that would occur there.

TRIP DISTRIBUTION AND ASSIGNMENT TO THE ROADWAY NETWORK

The project site lies within a major highway system in north-central Queens, between the Grand Central Parkway (GCP), the Long Island Expressway (LIE), the Van Wyck Expressway, and the Whitestone Expressway. As mentioned, two new ramps are proposed which would provide inbound access to the sites from the northbound Van Wyck Expressway and outbound access from the sites to the southbound Van Wyck Expressway, and would continue access to the eastbound and westbound Grand Central Parkway, currently available via the existing ramp.

The volume of vehicular traffic generated by the proposed project during each phase of development was assigned to the highway and roadway networks using regional and local origin/destination patterns attributed to the proposed land use types. Trips generated by the proposed land uses within the District were assigned to its primary access points. The route assignments for vehicular trips generated by the proposed project under each phase of buildout

assume only those ramp access improvements and street network changes that would be in place within the District by that Build year. However, while site access patterns would vary to a degree under each phase, overall origin-destination assignments would be similar. Similar to the travel demand assumptions, vehicle trip assignments generally reflect those used in the 2008 FGEIS.

OFFICE TRIPS

For office auto trips, 16 percent were assigned to the eastbound GCP, 2 percent were assigned to eastbound Astoria Boulevard, 5 percent were assigned to eastbound Northern Boulevard, 2 percent were assigned to eastbound Roosevelt Avenue, 4 percent were assigned to the eastbound LIE, 20 percent were assigned to the westbound Grand Central Parkway (from south of the LIE); 16 percent were assigned to the westbound LIE, 17 percent were assigned to the southbound Whitestone Expressway, 14 percent were assigned to the northbound Van Wyck Expressway (from south of the LIE); 2 percent were assigned to westbound Northern Boulevard, and a combined 2 percent were assigned to westbound Roosevelt Avenue, westbound Sanford Avenue, and College Point Boulevard. Office taxi trips were assigned with approximately 65 to 70 percent on the highways and the remaining 30 to 35 percent on local streets through the study area, following similar routes as auto trips.

RETAIL TRIPS

Separate trip distribution patterns were estimated for destination retail trips, local retail trips, and the movie theatre trips. Overall, considering all retail uses, for retail trips traveling to the project site from points west of the study area (Manhattan, the Bronx/Westchester, and western/west-central Queens, and surrounding neighborhoods), it was estimated that about 8 to 16 percent would use the eastbound GCP, about 5 to 8 percent would use eastbound Astoria Boulevard, 6 to 12 percent would use eastbound Northern Boulevard, about 3 to 8 percent would use Roosevelt Avenue, and about 6 to 12 percent would use the eastbound LIE. For retail trips traveling to the project site from points east of the study area (eastern/southeastern Queens, Long Island, and surrounding neighborhoods), it was estimated that about 5 to 6 percent would use the westbound GCP, 5 to 10 percent would use westbound Northern Boulevard, about 1 to 5 percent would use westbound Roosevelt Avenue, 1 to 3 percent would use westbound Sanford Avenue, and 10 to 16 percent would use the westbound LIE. For retail trips traveling to the project site from points north of the study area (northeastern Queens, the Bronx, and surrounding neighborhoods), it was estimated that about 8 to 12 percent would use the southbound Whitestone Expressway, up to 1 percent would use southbound College Point Boulevard, and up to 3 percent would use Parsons Boulevard. For retail trips traveling to the project site from points south of the study area (southern Queens, Brooklyn, and surrounding neighborhoods), it was estimated that about 5 to 14 percent would use the northbound Van Wyck Expressway, up to 2 percent would use northbound College Point Boulevard, up to 4 percent would use Kissena Boulevard/Main Street, up to 3 percent would use northbound Parsons Boulevard, and up to 1 percent would use 108th Street. Overall, destination retail and movie theater taxi trips were assigned with approximately 55 to 60 percent on the highways and the remaining 40 to 45 percent on local streets through the study area, following similar routes as auto trips.

CONVENTION CENTER TRIPS

It is expected that a convention center at Willets Point would have regional attractiveness, with trips predominantly on the highway network to the study area. For the convention center, approximately 12 to 18 percent of the trips would be on each of the major highways to the study area, including the eastbound and westbound GCP, the eastbound and westbound LIE, the northbound Van Wyck Expressway, and the southbound Whitestone Expressway. Use of the local streets, including Northern Boulevard, Roosevelt Avenue, and College Point Boulevard, would range from 1 to 6 percent.

Convention center taxi trips were assigned with approximately 90 percent on the highways and the remaining 10 percent on local streets through the study area, following similar routes as auto trips.

HOTEL TRIPS

Regional distributions for hotel trips are expected to be generally similar to those of the convention center, but with a somewhat higher use of the local street network through the study area. It is expected that hotel trip distributions on the highway network would be about 10 to 18 percent on each highway to the District, and local street use would range from 1 to 8 percent each on Astoria Boulevard, Northern Boulevard, Roosevelt Avenue, Sanford Avenue, and College Point Boulevard. Hotel taxi trips were assigned with approximately 75 percent on the highways and the remaining 25 percent on local streets through the study area, following similar routes as auto trips.

SCHOOL TRIPS

Student drop-off trips were assigned to the District from local streets and arterials serving surrounding neighborhoods. School “in” trips for the weekday AM peak hour were assigned as follows: about 10 to 18 percent each on eastbound Astoria Boulevard, eastbound and westbound Northern Boulevard, and eastbound Roosevelt Avenue; and about 2 to 8 percent each on westbound Roosevelt Avenue, westbound Sanford Avenue, Parsons Boulevard in both directions, southbound Union Street, Kissena Boulevard/Main Street, College Point Boulevard in both directions, and 34th Avenue. The small number of faculty trips to the school was assumed to follow similar routes as the weekday AM “in” distributions.

It was assumed that many of the drop-off trips would proceed to places to work; therefore, school “out” trips for the weekday AM peak hour were partly assigned according to morning commuter patterns (weekday AM peak hour residential “out” trip assignments). Weekday PM pick-up “in” trips would arrive along the reverse of the weekday AM “out” trips, and the pick-up “out” trips would route back to the origins of the weekday AM drop-off “in” trips.

COMMUNITY FACILITY/RECREATIONAL TRIPS

The community facility and recreational facilities are expected to serve surrounding neighborhoods, and therefore trips were assigned to the District from local streets and arterials similar to the weekday AM “in”/weekday PM “out” school trips. The very small number of expected community center taxi trips was assigned to Northern Boulevard.

DELIVERIES

Trucks were assigned along NYCDOT-designated truck routes, including the Van Wyck and Whitestone Expressways, the LIE, Northern Boulevard, Astoria Boulevard, Roosevelt Avenue, and College Point Boulevard (trucks are not allowed on the GCP). Overall on the highways, approximately 10 to 15 percent of all truck trips were assigned to the Van Wyck Expressway (south of the LIE), approximately 10 to 15 percent were assigned to the Whitestone Expressway, and approximately 20 to 25 percent were assigned to each the eastbound and westbound LIE (these trucks would access the project area along the Van Wyck Expressway). For local streets, about 10 to 15 percent were assigned to Astoria Boulevard, about 2 to 10 percent were assigned to each eastbound and westbound Northern Boulevard, and about 1 to 5 percent were assigned to Roosevelt Avenue and College Point Boulevard.

GAME DAY CIRCULATION CHANGES

In 2018, the proposed Phase 1A development would displace approximately 4,100 parking spaces from the main CitiField parking lot to make way for the proposed Willets West development. For

the Phase 1A With Action scenario, the displaced parking spaces would be replaced by approximately 2,750 parking spaces provided in a new interim lot located on the east side of 126th Street between Roosevelt Avenue and 35th Avenue, and an additional 950 parking spaces in a new garage located on the South Lot (south side of Roosevelt Avenue between west of 126th Street). The remaining 400 parking spaces would be located within the new Willets West parking facilities. For Phase 1A, game traffic that currently parks at the main CitiField parking lot was reassigned to each of the proposed new CitiField lots. During pre-game conditions, it is expected that fans would originate from the same areas and access the study area via the same highways as in existing conditions. However, due to the proximity of the proposed new South Lot parking garage to the westbound Grand Central Parkway off-ramps, a portion of fans that currently use the northbound Van Wyck Expressway to access the stadium were reassigned from the northbound Van Wyck Expressway to the westbound Grand Central Parkway via Exit 10 (south of the Long Island Expressway). The remaining fans that currently use the northbound Van Wyck Expressway would continue to access CitiField parking via the westbound Northern Boulevard exit and through the World's Fair Marina and local roadway network. In addition, a portion of fans that arrive at the stadium via the westbound Grand Central Parkway ramps to 126th Street are expected to exit the highway further south at Exit 9P or via the ramp to West Park Loop/Stadium Road and proceed to the proposed parking facilities. The remaining fans are expected to continue using the same access points as in existing conditions, but have been locally re-routed to the proposed new parking facilities via the most direct routes. During the post-game conditions under Phase 1A, it is expected that fans would travel the same outbound routes as in existing conditions, but would use alternate ramps depending on their proximity to the new parking lots.

By Phase 1B in 2028 and thereafter, the proposed new ramps linking the northbound and southbound Van Wyck Expressway with the District would be operational, and the temporary CitiField parking lot within the District in Phase 1A would be removed. All CitiField parking spaces that were displaced in Phase 1A would be replaced in three parking garages located on South Lot and Lot D. For Phase 1B and Phase 2, game traffic using the main CitiField parking lot in existing conditions was diverted to the proposed new CitiField parking facilities. During pre-game conditions, the same portion of game traffic that was reassigned from the northbound Van Wyck Expressway to the westbound Grand Central Parkway in Phase 1A would continue to use the westbound Grand Central Parkway since it is the most direct route to the proposed new garages. The portion of game traffic that would continue to use the northbound Van Wyck Expressway was reassigned to the proposed new ramp into the District and to the proposed new parking garages via local streets. As in Phase 1A, a portion of fans that arrive at the stadium via the westbound Grand Central Parkway ramps to 126th Street are expected to exit the highway further south at Exit 9P or via the ramp to West Park Loop/Stadium Road and proceed to the proposed parking facilities. A portion of fans that currently access the stadium via Astoria Boulevard and Northern Boulevard ramps to 126th Street were reassigned to the proposed new garages via southbound 114th Street to Roosevelt Avenue. During the post-game conditions, it is expected that fans would travel the same outbound routes as in existing conditions, but would use alternate ramps depending on their proximity to the new parking lots.

TRAFFIC LEVELS OF SERVICE AND SIGNIFICANT IMPACT CRITERIA

The assessment of potential significant traffic impacts of the proposed project is based on significant impact criteria defined in the *CEQR Technical Manual*. No Action LOS A, B, or C conditions that deteriorate to unacceptable LOS D, E, or F in the future With Action conditions are considered a significant traffic impact. For future No Action LOS A, B, or C conditions that deteriorate to unacceptable LOS D, mitigation to mid-LOS D (45.0 seconds of delay for

signalized intersections and 30.0 seconds of delay for unsignalized intersections) needs to be considered to fully mitigate the impact.

For a No Action LOS D, an increase of delay by five or more seconds in the With Action condition is considered a significant impact if the With Action condition delay meets or exceeds 45.0 seconds. For a No Action LOS E, the threshold is a four second increase in With Action condition delay; for a No Action LOS F, a three second increase in delay in the With Action condition is significant. For unsignalized intersections, for the minor street to generate a significant impact, 90 passenger car equivalents (PCEs) must be identified in the With Action condition in any peak hour.

Detailed summaries of traffic levels of service for analyzed intersections and identification of significant traffic impacts for conditions in the future with the proposed project under each phase of buildout are presented in the sections below.

PHASE 1A (2018) TRAFFIC ANALYSIS RESULTS

This section includes a determination of the volume of vehicle trips generated under the Phase 1A 2018 With Action condition, their distribution within the study area roadway network, the analysis of future traffic levels of service, and the identification of significant impacts as per *CEQR Technical Manual* guidelines. Mitigation measures are discussed in Chapter 21.

TRAVEL DEMAND ANALYSIS

As mentioned earlier, proposed development expected to be built out under Phase 1A includes a substantial amount of destination retail including a movie theater and a parking garage (2,900 spaces) on the Willetts West site and a smaller amount of hotel and local retail uses, and a surface parking lot (2,825 spaces)/off-season recreational space in the Special Willetts Point District. This program is detailed in **Table 14-31**.

Table 14-31
Phase 1A (2018) Buildout Development Program for Analysis

Use	Size
Willetts West ⁽¹⁾	
Destination Retail Movie Theater	915,000 SF 4,000 Seats (80,000 SF) ⁽²⁾
Special Willetts Point District	
Local Retail Hotel Recreational Uses ⁽³⁾	30,000 SF 200 Rooms 20 Acres
Total	
Destination Retail Movie Theater Local Retail Hotel Recreational Uses	915,000 SF 4,000 Seats 30,000 SF 200 Rooms 20 Acres
Notes:	
(1) Willetts West would contain approximately 1.4 million sf of development, including 400,000 sf of non-leasable common area. This ancillary space is not considered for trip generation purposes.	
(2) <i>Willetts Point Development Plan FGEIS</i> (2008) assumption of 20 sf per seat.	
(3) Temporary use. Would be replaced by 2028 with other uses. Programmed only during non-game days and the off-season.	
SF = square feet; DU = dwelling unit	

The volume of person trips and vehicle trips expected to be generated under Phase 1A of the proposed project would be substantial. **Table 14-32** presents the person trips generated by the

proposed project, and shows that it would generate an estimated 2,658, 8,336, 8,554, and 11,657 person trips during the weekday AM, midday, PM, and Saturday midday (non-game day) peak hours, respectively. On game days, the proposed project would generate an estimated 7,751 person trips during the weekday PM pre-game peak hour and 8,675 and 7,732 person trips in the Saturday pre-game and post-game hours, respectively.

Table 14-33 presents the vehicle trip estimates for the proposed project. The project would generate a total of 883, 2,517, 2,618, and 3,132 vehicle (auto, taxi, and delivery) trips during the weekday AM, midday, PM, and Saturday midday (non-game day) peak hours, respectively. On game days, the project would generate an estimated 2,324 vehicle trips during the weekday PM pre-game peak hour and 2,313 and 2,063 vehicle trips in the Saturday pre-game and post-game hours, respectively. The proposed project's taxi trips were adjusted based on the assumption that 25 percent of the arriving taxis would depart with a fare, per *CEQR Technical Manual* guidelines for this area.

TRAFFIC VOLUMES AND LEVELS OF SERVICE

Vehicle trips generated in Phase 1A were assigned through the study area based on the trip assignments discussed earlier, and produced specific roadway-by-roadway and intersection-by-intersection traffic volume projections within the study area. An overview of this is provided below, and specific and intersection-by-intersection generated volume projections are provided in detail in the technical appendices at the end of this chapter.

In 2018, the Phase 1A generated traffic volume increments would make up approximately 4 percent of the overall traffic volumes in the AM peak hour, 11 percent in the midday peak hour, 9 percent in the PM peak hour, and 11 percent in the Saturday midday peak hour, without a Mets game, when comparing these volume increments to overall Phase 1A With Action traffic volumes entering and exiting the traffic study area's local street network. For conditions with a Mets game, the proposed project's traffic increments would make up about 8 percent of the overall traffic volumes during all peak hours.

Northern Boulevard volumes can be expected to increase by about 20 to 115 vph per direction during the peak analysis hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Northern Boulevard volumes can be expected to increase by approximately 25 to 515 vph per direction during all of the peak hours, with the increase in traffic along this section of the roadway primarily due to traffic from the ramp from the southbound Whitestone Expressway onto westbound Northern Boulevard. Northern Boulevard volumes in the vicinity of 108th and 114th Street can be expected to increase by about 20 to 125 vph per direction during the peak analysis hours.

Roosevelt Avenue volumes can be expected to increase by about 10 to 55 vph per direction during the non-game and game peak hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Roosevelt Avenue volumes can be expected to increase by approximately 15 to 150 vph per direction during the peak hours without a Mets game—with the highest increment due mostly to retail trips during the Saturday midday peak hour, and by about 55 to 115 vph per direction during the peak hours with a Mets game. Roosevelt Avenue volumes in the vicinity of 108th, 111th, and 114th Streets can be expected to increase by about 20 to 150 vph per direction during the peak analysis hours.

Sanford Avenue volumes through Downtown Flushing between Parsons Boulevard and College Point Boulevard can be expected to increase by about 4 to 45 vph per direction during the peak analysis hours.

Astoria Boulevard volumes in the vicinity of 108th and 114th Streets can be expected to increase by about 50 to 95 vph per direction during the peak analysis hours.

Volumes on 34th Avenue from the District at the intersection with 126th Street are not expected to increase. However, volumes along West Park Loop/Stadium Road at the intersection with 126th

Willets Point Development

Street can be expected to increase by approximately 70 to 390 vph per direction during the peak hours without a Mets game, and by 170 to 315 vph per direction during the peak hours with a Mets game.

Volumes along 126th Street in the vicinity of 34th Avenue can be expected to increase by approximately 50 to 150 vph per direction during the peak analysis hours. In the vicinity of Roosevelt Avenue, 126th Street volumes can be expected to increase by about 15 to 65 vph per direction during the peak analysis hours.

College Point Boulevard volumes can be expected to increase by about 5 to 60 vph per direction during the peak analysis hours.

Volumes along 114th Street in the vicinity of Roosevelt Avenue can be expected to increase by approximately 25 to 225 vph per direction during the peak analysis hours. Projected volume increments on the other north-south streets, including 108th Street, Main Street, Union Street, and Parsons Boulevard can be expected to 40 vph per direction or less during all of the peak hours.

The remainder of this section provides an overview of significant traffic impacts that would be generated under the With Action conditions. Detailed volume-to-capacity (v/c) ratios, average vehicle delays, and levels of service movement-by-movement at each intersection under the Phase 1A (2018) With Action condition are presented at the end of this chapter. Project-generated traffic volume increment maps and total With Action volume maps are provided within **Appendix C**.

Using the previously discussed volume increases, the levels of service for the Phase 1A With Action condition were determined for ~~29~~ 32 of the ~~34~~ 34 intersections (both signalized and unsignalized) analyzed under the No Action condition. Two unsignalized intersections, Willets Point Boulevard at 126th Street and Boat Basin Road at Stadium Road, analyzed under the No Action condition, would be eliminated due to street demapping and intersection improvements in the proposed project under Phase 1A. Future traffic levels of service under the With Action condition are shown in **Tables 14-34** through **14-37**.

Table 14-34
Overall Intersection Level of Service Summary Comparison
Phase 1A (2018) No Action vs. With Action Conditions—Non-Game Day

	Phase 1A No Action Condition				Phase 1A With Action Condition			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
Signalized Intersections	26 Signalized Intersections				26 28 Signalized Intersections			
Overall Intersection LOS A/B/C	13 <u>14</u>	15	13 <u>12</u>	15	14 <u>13</u>	12 <u>14</u>	14 <u>12</u>	14 <u>12</u>
Overall Intersection LOS D	5 <u>4</u>	6	7 <u>8</u>	3	6 <u>5</u>	4	4 <u>5</u>	4
Overall Intersection LOS E	8	2	4	6	9 <u>10</u>	4	7	1
Overall Intersection LOS F	0	3	2	2	0	6	4	10 <u>11</u>
No. of Locations with Significant Impacts	--	--	--	--	14	15 <u>14</u>	19	18
Notes: During the non-game peak hours in the Phase 1A With Action condition, one of the three <u>four</u> unsignalized intersections analyzed would be significantly impacted in the weekday AM and PM peak hours, and two unsignalized intersections would be impacted during the weekday and Saturday midday peak hours.								

Table 14-35

Traffic Lane Group Level of Service Summary Comparison
Phase 1A (2018) No Action vs. With Action Conditions—Non-Game Day

Signalized Movements	Phase 1A No Action Condition				Phase 1A With Action Condition			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				26 28 Signalized Intersections			
No. of Lane Groups at LOS A/B/C	62	76 77	63	74	62 69	70 78	57 65	64 72
No. of Lane Groups at LOS D	35 37	28	32 34	23 25	35 39	28 31	36	34 33
No. of Lane Groups at LOS E	15 13	9	12 11	13 12	14 13	13 12	11	14 10
No. of Lane Groups at LOS F	47 18	17	22	20	20 21	22 23	29 32	28 30
Notes: During the non-game peak hours in the Phase 1A With Action conditions, one of the ten 11 unsignalized lane groups analyzed would operate at LOS F in the weekday AM peak hour, three lane groups would operate at LOS F in the midday and PM peak hours, and four lane groups would operate at LOS F in the Saturday midday peak hour. All other unsignalized lane groups would operate at LOS D or better during non-game peak hours.								

Table 14-36

Overall Intersection Level of Service Summary Comparison
Phase 1A (2018) No Action vs. With Action Conditions—Game Day

Signalized Intersections	Phase 1A No Action Condition			Phase 1A With Action Condition		
	Weekday Pre-game	Weekend Pre-game	Weekend Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 28 Signalized Intersections		
Overall Intersection LOS A/B/C	11 10	13	10	9 8	12 11	9
Overall Intersection LOS D	7 8	4	5	7 9	4 2	4
Overall Intersection LOS E	6	5	8	5 4	4 5	3
Overall Intersection LOS F	2	4	3	5 7	9 10	10 12
No. of Locations with Significant Impacts	--	--	--	49 21	45 17	48 20
Notes: During the game day peak hours in the Phase 1A With Action condition, two of the three <u>four</u> unsignalized intersections analyzed would be significantly impacted in the weekday and Saturday pre-game peak hours, and one unsignalized intersection would be impacted during the weekday Saturday post-game peak hour.						

Table 14-37

Traffic Lane Group Level of Service Summary Comparison
Phase 1A (2018) No Action vs. With Action Conditions—Game Day

Signalized Movements	Phase 1A No Action Condition			Phase 1A With Action Condition		
	Weekday Pre-game	Weekend Pre-game	Weekend Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			26 28 Signalized Intersections		
No. of Lane Groups at LOS A/B/C	61 60	72 73	72 73	53 56	65 69	70 73
No. of Lane Groups at LOS D	37 40	25	20 21	36 40	31 34	47 19
No. of Lane Groups at LOS E	44 10	8	9 8	46 19	8 9	13
No. of Lane Groups at LOS F	21	25	29	26 29	28 33	32 38
Notes: During the game day peak hours in the Phase 1A With Action conditions, one of the ten 11 unsignalized lane groups analyzed would operate at LOS F and one lane group would operate at LOS E in the weekday pre-game peak hour, and three lane groups would operate at LOS F and one lane group would operate at LOS E in the Saturday pre- and post-game peak hours. All other unsignalized lane groups would operate at LOS A, <u>or</u> B, <u>or</u> C during game day peak hours.						

The addition of the proposed project's generated traffic for Phase 1A to the already poor future baseline (2018 No Action) conditions would result in relatively few new intersections or lane groups operating at unacceptable levels of service; however, it would cause several already sensitive locations to be significantly impacted. As a result, Phase 1A of the proposed project would have significant traffic impacts at 14 of the ~~26~~ 28 signalized intersections analyzed in the weekday AM peak hour, ~~45~~ 14 of ~~26~~ 28 in the weekday midday peak hour, 19 of ~~26~~ 28 in the

weekday PM peak hour, and 18 of ~~26~~ 28 in the non-game Saturday midday peak hour. During the weekday pre-game peak hour, ~~49~~ 21 of ~~26~~ 28 signalized intersections analyzed would have significant traffic impacts, during the Saturday pre-game peak hour ~~15~~ 17 of ~~26~~ 28 signalized intersections analyzed would have significant impacts, and during the Saturday post-game peak hour ~~18~~ 20 of ~~26~~ 28 signalized intersections analyzed would have significant impacts. Of the ~~three~~ four unsignalized intersections analyzed, one (World's Fair Marina at Boat Basin Road) would be significantly impacted in each of the peak analysis hours.

The summary overview of the Phase 1A With Action condition without a Mets game indicates that:

- In the weekday AM peak hour, ~~9~~ 10 of the ~~26~~ 28 analyzed signalized intersections are projected to operate at overall LOS E or F, which is ~~one~~ two more than under the No Action condition. Fourteen signalized intersections would be significantly impacted. The number of traffic lane groups that are expected to operate at LOS E or F would increase from ~~32~~ 31 to 34.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from five under the No Action condition to ten under the With Action condition, and there would be significant impacts at ~~15~~ 14 of the ~~26~~ 28 signalized intersections. The number of individual lane groups that would operate at LOS E or F would increase from 26 to 35.
- In the weekday PM peak hour, the number of intersections that are projected to operate at overall LOS E or F would increase from 6 to 11 under the With Action condition, with 19 signalized intersections significantly impacted. The number of individual lane groups that would operate at LOS E or F would increase from ~~34~~ 33 to ~~40~~ 43.
- In the Saturday midday peak hour, the number of signalized intersections projected to operate at LOS E or F would increase from 8 under the No Action condition to ~~11~~ 12 under the With Action condition. Eighteen signalized intersections would be significantly impacted. The number of lane groups at LOS E or F would increase from ~~33~~ 32 to ~~39~~ 40.
- Two of the ~~three~~ four unsignalized intersections would be significantly impacted during at least one peak hour. World's Fair Marina at Boat Basin Road would consistently have a traffic lane group (northbound Boat Basin Road left turn movement) operate at LOS F during the weekday AM, midday, PM, and Saturday midday non-game peak hours and, as a result, would be significantly impacted in all non-game-day peak hours. Also, Stadium Road/West Loop Road at the Grand Central Parkway exit ramp—which would be reconfigured with a new west leg that would serve as an entrance/exit in and out of the proposed Willets West retail development—would have several movements that operate at unacceptable levels of service, one of which (the eastbound left turn movement from the GCP off-ramp) would be significantly impacted during the weekday and Saturday midday peak hours.

The summary overview of the Phase 1A With Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, ~~10~~ 11 out of ~~26~~ 28 signalized intersections would operate at LOS E or F under the With Action condition, which is an increase from eight signalized intersections at LOS E or F under the No Action condition. There would be significant impacts at ~~19~~ 21 of the ~~26~~ 28 signalized intersections. The number of lane groups that would operate at LOS E or F would increase from ~~32~~ 31 to ~~42~~ 48.

- During the Saturday midday pre-game peak hour, the number of intersections that are expected to operate at LOS E or F would increase from 9 to ~~13~~ 15 under the With Action condition, with ~~15~~ 17 signalized intersections significantly impacted. The number of lane groups at LOS E or F would increase from 33 to ~~36~~ 42.
- In the Saturday PM post-game peak hour, the number of locations that would operate at LOS E or F would increase from 11 to ~~13~~ 15 under the With Action condition. ~~Eighteen~~ Twenty signalized intersections would be significantly impacted. The number of lane groups that would operate at LOS E or F would increase from ~~38~~ 37 to ~~45~~ 51.

Two of the ~~three~~ four unsignalized intersections would be significantly impacted during at least one peak hour. At World's Fair Marina at Boat Basin Road, the northbound Boat Basin Road left turn movement would consistently operate at LOS F during all game day peak hours, and would be significantly impacted. At the reconfigured intersection of Stadium Road/West Loop Road at the Grand Central Parkway exit ramp, the eastbound left turn movement from the GCP off-ramp would operate at LOS E during all peak hours and would be significantly impacted during the weekday and Saturday pre-game peak hours. Additionally, two intersections that were unsignalized in the No Action condition would be significantly impacted as signalized intersections in the With Action condition during all game peak hours.

Table 14-38 shows the locations and time periods where significant impacts would occur in the Phase 1A (2018) With Action condition. Mitigation measures for significantly impacted locations are discussed in Chapter 21, ~~"Mitigation."~~

PHASE 1A (2018) WITH ACTION PARKING

In Phase 1A, the proposed project would provide approximately 2,500 off-street accessory parking spaces to satisfy the projected parking demand due to the development in Willets West and 75 accessory spaces for project demand in the District.¹ As shown in **Table 14-39**, the projected weekday and Saturday peak parking demands for Willets West (1,127 and 2,238 spaces, respectively) is anticipated to be satisfied entirely by the off-street parking facility provided within the site.

¹ Additional parking spaces may be provided for off-season recreation uses within the District if they are warranted.

Source: Based on travel demand estimates														

As shown in **Tables 14-40** and **14-41**, parking demand from development within the District would not be fully accommodated by the 75 accessory spaces on weekdays or on Saturdays. During the Mets off-season, there would be an additional parking demand of 5 to 131 spaces on weekdays and Saturdays. During the off-season when the recreational uses would be in place, the additional recreational accessory parking demand, if needed, would be provided in Lot B, the north lot, or within the Willets Point District property itself to satisfy this demand.

During the Mets season, the weekday and Saturday parking shortfalls would be substantially lower since there would be no parking demand generated by the recreational uses. On weekdays, there would be a slight overnight shortfall (between 10 PM and 8 AM) of 5 to 17 spaces, and a midday shortfall of 3 to 37 spaces. On Saturday, there would be a slight shortfall during most of the day ranging from 4 to 33 spaces. It is expected that this shortfall would be fully absorbed by publicly available on- and off-street spaces within and near the District.

In addition to providing accessory parking for project demand, the proposed Phase 1A program would also include the in-kind replacement of 4,100 Mets parking spaces in the main CitiField lots that would be displaced by the Willets West development. These replacement spaces would be distributed amongst a new parking facility in the District (2,750 spaces, used as recreational space in the off-season), Lot D/South Lot (950 spaces) and the Willets West development (400 spaces).

PHASE 1B (2028) TRAFFIC ANALYSIS RESULTS

This section includes a determination of the volume of vehicle trips generated under the Phase 1B 2028 With Action condition, their distribution within the study area roadway network, the analysis of future traffic levels of service, and the identification of significant impacts as per *CEQR Technical Manual* guidelines. Mitigation measures are discussed in Chapter 21.

TRAVEL DEMAND ANALYSIS

The proposed development expected to be built out under Phase 1B includes the Willets West development (as built by Phase 1A) consisting of destination retail with a movie theater and a parking garage (2,900 spaces), and a substantial amount of the total proposed development in the Special Willets Point District. This includes residential, retail, office, hotel, and community facility uses which would replace the interim surface parking/recreational space developed under the Phase 1A program (parking would be relocated to the lot south of Roosevelt Avenue - the "South Lot"). This program is detailed in **Table 14-42**.

Table 14-42
Phase 1B (2028) Buildout Development Program for Analysis

Use		Size
Willets West ⁽¹⁾	Destination Retail	915,000 SF
	Movie Theater	4,000 Seats (80,000 SF) ⁽²⁾
Special Willets Point District	Residential	2,490 DU
	Destination Retail	588,300 SF
	Local Retail	316,700 SF
	Office	500,000 SF
	Hotel	490 Rooms
	Community Facility	25,000 SF
	Public School (K-8)	623 Seats
Total	Residential	2,490 DU
	Destination Retail	1,503,300 SF
	Movie Theater	4,000 Seats
	Local Retail	316,700 SF
	Office	500,000 SF
	Hotel	490 Rooms
	Community Facility	25,000 SF
	Public School (K-8)	623 Seats
Notes:		
(1) Willets West would contain approximately 1.4 million sf of development, including 400,000 sf of non-leasable common area. This ancillary space is not considered for trip generation purposes.		
(2) Willets Point Development Plan FGEIS (2008) assumption of 20 sf per seat.		
SF = square feet		
DU = dwelling unit		

The volume of person trips and vehicle trips expected to be generated under Phase 1B of the proposed project would be substantial. **Table 14-43** presents the person trips generated by the proposed project, and shows that Phases 1A and 1B together would generate an estimated 9,812, 23,284, 20,826, and 25,024 person trips during the weekday AM, midday, PM, and Saturday midday (non-game days) peak hours, respectively. On game days, the proposed project would generate an estimated 16,673 person trips during the weekday PM pre-game peak hour and 20,222 and 18,239 person trips in the Saturday pre-game and post-game hours, respectively.

Table 14-44 presents the vehicle trip estimates for the proposed project. The project would generate a total of 2,649, 5,152, 5,420, and 5,855 vehicle (auto, taxi, and delivery) trips during the weekday AM, midday, PM, and Saturday midday (non-game day) peak hours, respectively. On game days, the project would generate an estimated 4,194 vehicle trips during the weekday PM pre-game peak hour and 4,576 and 4,037 vehicle trips in the Saturday pre-game and post-game hours, respectively. The proposed project's taxi trips were adjusted based on the assumption that 25 percent of the arriving taxis would depart with a fare, per *CEQR Technical Manual* guidelines for this area.

TRAFFIC VOLUMES AND LEVELS OF SERVICE

Vehicle trips generated under Phase 1B buildout conditions were assigned through the study area based on the trip assignments discussed earlier, and produced specific roadway-by-roadway and intersection-by-intersection traffic volume projections within the study area. An overview of this is provided below, and specific intersection-by-intersection generated volume projections are provided in detail in the technical appendices at the end of this chapter.

In 2028, generated traffic volume increments would make up approximately 10 percent of the overall traffic volumes in the AM peak hour, 20 percent in the midday peak hour, 18 percent in the PM peak hour, and 20 percent in the Saturday midday peak hour, without a Mets game, when comparing these volume increments to overall Phase 1B With Action traffic volumes entering and exiting the traffic study area's local street network. For peak hours with a Mets game, the proposed project's traffic increments would make up about 13 percent and 15 percent of the overall traffic volumes during the weekday PM and Saturday midday pre-game peak hours, and about 14 percent during the Saturday PM post-game peak hour.

Northern Boulevard volumes can be expected to increase by about 50 to 200 vph per direction during the peak analysis hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Northern Boulevard volumes can be expected to increase by approximately 20 to 225 vph in the eastbound direction and 50 to 875 vph in the westbound direction during the peak analysis hours, with the increase in traffic along this section of the roadway primarily due to traffic from the ramp from the southbound Whitestone Expressway onto westbound Northern Boulevard. Northern Boulevard volumes in the vicinity of 108th and 114th Street can be expected to increase by about 80 to 235 vph per direction during the peak analysis hours.

Roosevelt Avenue volumes can be expected to increase by about 25 to 90 vph per direction during the non-game and game peak hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Roosevelt Avenue volumes can be expected to increase by approximately 75 to 330 vph per direction during the peak hours without a Mets game and by about 115 to 275 vph per direction during the peak hours with a Mets game. Roosevelt Avenue volumes in the vicinity of 108th, 111th, and 114th Streets can be expected to increase by about 45 to 130 vph per direction during the peak analysis hours.

Sanford Avenue volumes through Downtown Flushing between Parsons Boulevard and College Point Boulevard can be expected to increase by up to 15 vph in the eastbound direction and 15 to 70 vph in the westbound direction during the peak analysis hours.

Astoria Boulevard volumes in the vicinity of 108th and 114th Streets can be expected to increase by about 45 to 160 vph per direction during the peak analysis hours.

Volumes on 34th Avenue to/from the District at the intersection with 126th Street are expected to increase by 150 to 350 vph during all seven peak hours, and volumes along West Park Loop/Stadium Road at the intersection with 126th Street can be expected to increase by approximately 150 to 635 vph per direction during the peak analysis hours.

Volumes along 126th Street in the vicinity of 34th Avenue can be expected to increase by approximately 255 to 410 vph per direction during non-game peak hours, and 170 to 635 vph during game day peak hours. In the vicinity of Roosevelt Avenue, 126th Street volumes can be expected to increase by about 100 to 300 vph per direction during the peak analysis hours.

College Point Boulevard volumes can be expected to increase by about 10 to 110 vph per direction during the peak analysis hours.

Volumes along 114th Street in the vicinity of Roosevelt Avenue can be expected to increase by approximately 50 to 280 vph in the northbound direction and 15 to 40 vph in the southbound direction during the peak analysis hours. Projected volume increments on the other north-south streets, including 108th Street, Main Street, Union Street, and Parsons Boulevard can be expected to 60 vph per direction or less during the peak analysis hours.

The remainder of this section provides an overview of significant traffic impacts that would be generated under 2028 With Action conditions. Detailed volume-to-capacity (v/c) ratios, average vehicle delay, and levels of service movement-by-movement at each intersection under the 2028 With Action conditions are provided at the end of this chapter. Project-generated traffic volume increment maps and total With Action volume maps are provided in **Appendix C**.

Levels of service for 2028 With Action conditions were determined for 29 of the 31 intersections (both signalized and unsignalized) analyzed under the No Action condition. Two unsignalized intersections, Willets Point Boulevard at 126th Street and Boat Basin Road at Stadium Road, analyzed under the No Action condition, would be eliminated due to street demapping and intersection improvements, and one new signalized intersection—126th Street at New Willets Point Boulevard—would be created as part of the proposed project under Phase 1B. Future traffic levels of service under the With Action condition are shown in **Tables 14-45** through **14-48**.

The addition of the proposed project's generated traffic for Phase 1B to the already poor future baseline (2028 No Action) conditions would cause several already sensitive locations to be significantly impacted. As a result, Phase 1B of the proposed project would have significant traffic impacts at 18 of the ~~27~~ 29 signalized intersections analyzed in the weekday AM peak hour, ~~18~~ 19 of ~~27~~ 29 in the weekday midday peak hour, 19 of ~~27~~ 29 in the weekday PM peak hour, and 22 of ~~27~~ 29 in the non-game Saturday midday peak hour. During the weekday pre-game peak hour, 20 of ~~27~~ 29 signalized intersections analyzed would have significant traffic impacts, during the Saturday pre-game peak hour ~~18~~ 19 of ~~27~~ 29 signalized intersections analyzed would have significant impacts, and during the Saturday post-game peak hour ~~18~~ 20 of ~~27~~ 29 signalized intersections analyzed would have significant impacts. Of the ~~three~~ four unsignalized intersections analyzed, one (World's Fair Marina at Boat Basin Road) would be significantly impacted in each of the peak analysis hours.

Table 14-45

**Overall Intersection Level of Service Summary Comparison
Phase 1B (2028) No Action vs. With Action Conditions—Non-Game Day**

No. of Locations with Significant Impacts	--	--	--	20	18 19	18 20
Notes: During the game day peak hours in the Phase 1B With Action condition, two of the three <u>four</u> unsignalized intersections analyzed would be significantly impacted in the weekday and Saturday pre-game peak hours, and one <u>three</u> unsignalized intersections would be impacted during the weekday <u>Saturday</u> post-game peak hour.						

Table 14-48

Traffic Lane Group Level of Service Summary Comparison
Phase 1B (2028) No Action vs. With Action Conditions—Game Day

Signalized Movements	Phase 1B No Action Condition			Phase 1B With Action Condition		
	Weekday Pre-game	Weekend Pre-game	Weekend Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			27 29 Signalized Intersections		
No. of Lane Groups at LOS A/B/C	59	68 <u>70</u>	69 <u>70</u>	48 <u>52</u>	60 <u>63</u>	61 <u>65</u>
No. of Lane Groups at LOS D	34 <u>36</u>	27 <u>28</u>	24 <u>27</u>	33 <u>37</u>	27 <u>34</u>	26 <u>31</u>
No. of Lane Groups at LOS E	46 <u>17</u>	7	9 <u>8</u>	46 <u>17</u>	40 <u>9</u>	42 <u>14</u>
No. of Lane Groups at LOS F	21	28	29	39 <u>40</u>	39 <u>40</u>	38
Notes: During the game day peak hours in the Phase 1B With Action conditions, five of the ten <u>eleven</u> unsignalized lane groups analyzed would operate at LOS F in all three <u>game day peak hours</u> the <u>weekday and Saturday pre-game peak hours</u> , and one lane group would operate at LOS E and four lane groups would operate at LOS F during the <u>Saturday post-game peak hour</u> . All other unsignalized lane groups would operate at LOS C or better during game day peak hours.						

The summary overview of the Phase 1B With Action condition without a Mets game indicates that:

- In the weekday AM peak hour, ~~44~~ 12 of the ~~27~~ 29 analyzed signalized intersections are projected to operate at overall LOS E or F, which is ~~three~~ four more than under the No Action condition. Eighteen signalized intersections would be significantly impacted. The number of traffic lane groups that are expected to operate at LOS E or F would increase from 33 to ~~42~~ 43.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from six under the No Action condition to ~~12~~ 13 under the With Action condition, and there would be significant impacts at ~~48~~ 19 of the ~~27~~ 29 signalized intersections. The number of individual lane groups that would operate at LOS E or F would increase from 27 to ~~47~~ 48.
- In the weekday PM peak hour, the number of intersections that are projected to operate at overall LOS E or F would increase from ~~9~~ 8 to ~~45~~ 16 under the With Action condition, with 19 signalized intersections significantly impacted. The number of individual lane groups that would operate at LOS E or F would increase from ~~35~~ 36 to ~~49~~ 51.
- In the Saturday midday peak hour, the number of signalized intersections projected to operate at LOS E or F would increase from 9 under the No Action condition to ~~43~~ 14 under the With Action condition. Twenty-two signalized intersections would be significantly impacted. The number of lane groups at LOS E or F would increase from ~~37~~ 36 to ~~55~~ 57.
- ~~All three~~ Two of the four analyzed unsignalized intersections would be significantly impacted during at least one peak hour. World's Fair Marina at Boat Basin Road would consistently have a traffic lane group (northbound Boat Basin Road left turn movement) operate at LOS F during the weekday AM, midday, PM, and Saturday midday non-game peak hours and, as a result, would be significantly impacted in all non-game-day peak hours. Also, Stadium Road/West Loop Road at the Grand Central Parkway exit ramp—which would be reconfigured with a new west leg that would serve as an entrance/exit in and out of the proposed Willets West retail development—would have several movements that operate at unacceptable levels of service, ~~two~~ one of which (the eastbound left turn movement ~~and right turn movement~~ from the GCP off-ramp) would be significantly impacted during at least one peak hour. ~~At the intersection of Northern Boulevard and Willets Point Boulevard, northbound Willets Point Boulevard would operate at LOS F and be significantly impacted during the weekday midday, PM, and Saturday midday peak hours. Additionally, one~~

intersection that was unsignalized in the No Action condition would be significantly impacted as a signalized intersection in the With Action condition during the weekday midday peak hour.

The summary overview of the Phase 1B With Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, 14 out of ~~27~~ 29 signalized intersections would operate at LOS E or F under the With Action condition, which is an increase from eight signalized intersections at LOS E or F under the No Action condition. There would be significant impacts at 20 of the ~~27~~ 29 signalized intersections. The number of lane groups that would operate at LOS E or F would increase from ~~37~~ 38 to ~~55~~ 57.
- During the Saturday midday pre-game peak hour, the number of intersections that are expected to operate at LOS E or F would increase from 11 to ~~13~~ 14 under the With Action condition, with ~~48~~ 19 signalized intersections significantly impacted. The number of lane groups at LOS E or F would increase from 35 to 49.
- In the Saturday PM post-game peak hour, the number of locations that would operate at LOS E or F would increase from 13 to 17 under the With Action condition. ~~Eighteen~~ Twenty signalized intersections would be significantly impacted. The number of lane groups that would operate at LOS E or F would increase from ~~38~~ 37 to ~~50~~ 52.
- ~~All three~~ Three of the four analyzed unsignalized intersections would be significantly impacted during at least one peak hour. At World's Fair Marina at Boat Basin Road, the northbound Boat Basin Road left turn movement would consistently operate at LOS F during the weekday pre-game and Saturday pre-game and post-game peak hours and would be significantly impacted. Stadium Road/West Loop Road at the Grand Central Parkway exit ramp would have multiple movements operate at unacceptable levels of service and would be significantly impacted during at least one peak hour. At the intersection of Northern Boulevard and Willetts Point Boulevard, ~~northbound Willetts Point Boulevard~~ eastbound Northern Boulevard service road would operate at LOS ~~EE~~ and be significantly impacted during the Saturday post-game peak hour. Additionally, one intersection that was unsignalized in the No Action condition would be significantly impacted as a signalized intersection in the With Action condition during the Saturday pre-game peak hour and two would be impacted during the Saturday post-game peak hour.

Table 14-49 shows the locations and time periods where significant impacts would occur in the Phase 1B (2028) With Action condition. Mitigation measures for significantly impacted locations are discussed in Chapter 21, ~~“Mitigation.”~~

PHASE 1B (2028) WITH ACTION PARKING

Under the proposed Phase 1B (2028) buildout, a total of 2,700 accessory off-street parking spaces would be provided to accommodate parking demand generated by proposed development within the District. It is also anticipated that on-street parking would be provided on existing and new streets expected to be in place within the District by 2028. As detailed street configurations and curbside parking regulations have not yet been defined, it is expected that some level of on-street parking would be available. The proposed regulations would be designed to satisfy the needs of adjacent land uses; metered parking would likely be installed adjacent to retail uses or other commercial buildings, alternate side regulations would likely be installed near residential uses, and curbside parking restrictions would likely be imposed near the hotel, community facilities, or along primary delivery routes. Specific regulations would be determined at a later date.

Table 14-49

Phase 1B (2028) With Action Condition Significant Impact Summary

Intersections	Without a Mets Game				With a Mets Game		
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Pre-game Weekday PM	Pre-game Saturday Midday	Post-game Saturday PM
Astoria Boulevard at 108th Street			x	x	x	x	x

<u>Northern Boulevard at 126th Place</u>							
<u>126th Street at 36th Avenue</u>						x	x
<u>126th Street at 37th Avenue</u>		x					x
Notes: "x" means the intersection would be significantly impacted. n/a means the intersection is new for With Action conditions.							

As was done in the 2008 FGEIS, project parking for residential use was separated from the other proposed uses. **Table 14-50** shows a peak residential parking demand of 1,320 spaces occurring overnight. Assuming 10 percent of residential trips would park on-street (as was assumed in the 2008 FGEIS), 1,188 of the parking spaces proposed within the District would be needed to satisfy the residential parking demand. Residential parking demand is typically lowest during the daytime hours when office, community uses, and primary school parking demands are at a maximum. Therefore, shared parking strategies would be implemented and, where possible, office, community, and primary school parking demands would use parking spaces vacated by residents during the daytime hours. This would maximize usage of vacant residential parking spaces during daytime hours and minimize the need for additional dedicated parking spaces for office, community, and primary school uses.

Note: Acc. = Accumulation													
Source: Based on travel demand estimates													

The remaining 1,512 spaces would be available for the other uses—destination retail, local retail, and hotel. Based on the total accumulation for these uses shown in **Tables 14-50** and **14-51**, there would be enough parking to satisfy demand for these uses on a weekday, but there would be an additional need for up to approximately 45 spaces on Saturday during the midday hours 2 to 4 PM. However, it is expected that this could be accommodated by available on-street spaces or by vacant residential parking spaces within the District should such shared parking arrangements be made. Alternatively, this could be satisfied by available spaces in off-street facilities within an approximate quarter-mile radius of the District.

Parking demand and supply in Willets West would be the same as in Phase 1A; as detailed in the Phase 1A (2018) Parking section (in **Table 14-39**), the 2,500 parking spaces provided would accommodate weekday and Saturday peak parking demands.

As in Phase 1A, all Mets parking displaced by the proposed project in Phase 1B (2028), would be replaced. There would continue to be 400 spaces in Willets West; however, the 2,750 interim spaces provided in the District under Phase 1A would be relocated to Lot D/South Lot in addition to the 950 spaces already provided there. In total, including the 1,795 existing spaces, there would be 5,495 parking spaces in Lot D/South Lot under Phase 1B.

PHASE 2 (2032) TRAFFIC ANALYSIS RESULTS

This section includes a determination of the volume of vehicle trips generated under the Phase 2 2032 With Action condition, their distribution within the study area roadway network, the analysis of future traffic levels of service, and the identification of significant impacts as per *CEQR Technical Manual* guidelines. Mitigation measures are discussed in Chapter 21.

TRAVEL DEMAND ANALYSIS

The proposed project is expected to be built out in its entirety under Phase 2. This cumulative development program includes the full Willets West development which would be built under Phase 1A in 2018, development proposed within the Special Willets Point District that would be developed within Phases 1A, 1B, and 2, and the proposed Lot B development (which assumes the same office/retail projected in the 2008 FGEIS). This program is detailed in **Table 14-52**.

The volume of person trips and vehicle trips expected to be generated under Phase 2 (full buildout) of the proposed project would be substantial. **Table 14-53** presents the person trips generated by the proposed project, and shows that it would generate an estimated 18,060, 37,141, 33,764, and 38,780 person trips during the weekday AM, midday, PM, and Saturday midday (non-game day) peak hours, respectively. On game days, the fully built-out proposed project would generate an estimated 26,312 person trips during the weekday PM pre-game peak hour and 32,206 and 30,152 person trips in the Saturday pre-game and post-game hours, respectively.

Table 14-54 presents the vehicle trip estimates for the proposed project. The project would generate a total of 4,533, 7,551, 8,361, and 8,740 vehicle (auto, taxi, and delivery) trips during the weekday AM, midday, PM, and Saturday midday (non-game days) peak hours, respectively. On game days, the project would generate an estimated 6,339 vehicle trips during the weekday PM pre-game peak hour and 6,981 and 6,445 vehicle trips in the Saturday pre-game and post-game hours, respectively. The proposed project's taxi trips were adjusted based on the assumption that 25 percent of the arriving taxis would depart with a fare, per the *CEQR Technical Manual* guidelines for this area.

Total	Residential Destination Retail Movie Theater Local Retail Office Hotel Community Facility Public School (K-8) 5,850 DU 1,756,500 SF 4,000 Seats 593,000 SF 780,000 SF 700 Rooms 150,000 SF 1,463 Seats
Notes:	
(1) Willets West would contain approximately 1.4 million sf of development, including 400,000 sf of non-leasable common area. This ancillary space is not considered for trip generation purposes.	
(2) Willets Point Development Plan FGEIS (2008) assumption of 20 sf per seat.	
SF = square feet	
DU = dwelling unit

TRAFFIC VOLUMES AND LEVELS OF SERVICE

Vehicle trips generated under full buildout conditions were assigned through the study area based on the trip assignments discussed earlier, and produced specific roadway-by-roadway and intersection-by-intersection traffic volume projections within the study area. An overview of this is provided below, and specific intersection-by-intersection generated volume projections are provided in detail in the technical appendices at the end of this chapter.

In 2032, project-generated traffic volume increments would make up approximately 17 percent of the overall traffic volumes in the AM peak hour, 29 percent in the midday peak hour, 26 percent in the PM peak hour, and 29 percent in the Saturday midday peak hour, without a Mets game, when comparing these volume increments to overall Phase 2 With Action traffic volumes entering and exiting the traffic study area's local street network. For peak hours with a Mets game, the proposed project's traffic increments would make up about 19 percent of the overall traffic volumes during the weekday PM pre-game peak hour, 22 percent during the Saturday midday pre-game peak hour, and about 21 percent during the Saturday PM post-game peak hour.

Northern Boulevard volumes can be expected to increase by about 90 to 300 vph per direction during the peak analysis hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Northern Boulevard volumes can be expected to increase by approximately 30 to 440 vph in the eastbound direction and 90 to 1,300 vph in the westbound direction during the peak analysis hours, with the increase in traffic along this section of the roadway primarily due to traffic from the ramp from the southbound Whitestone Expressway onto westbound Northern Boulevard. Northern Boulevard volumes in the vicinity of 108th and 114th Street can be expected to increase by about 150 to 340 vph per direction during the seven peak hours.

Roosevelt Avenue volumes can be expected to increase by about 30 to 125 vph per direction during the non-game and game peak hours through Downtown Flushing between Parsons Boulevard and College Point Boulevard. Adjacent to the project site, Roosevelt Avenue volumes

can be expected to increase by approximately 125 to 500 vph per direction during the peak hours without a Mets game and by about 150 to 415 vph per direction during the peak hours with a Mets game. Roosevelt Avenue volumes in the vicinity of 108th, 111th, and 114th Streets can be expected to increase by about 75 to 200 vph per direction during the peak analysis hours.

Sanford Avenue volumes through Downtown Flushing between Parsons Boulevard and College Point Boulevard can be expected to increase by up to 15 vph in the eastbound direction and 25 to 90 vph in the westbound direction during the peak analysis hours.

Astoria Boulevard volumes in the vicinity of 108th and 114th Streets can be expected to increase by about 7 to 215 vph per direction during the peak analysis hours.

Volumes on 34th Avenue to/from the District at the intersection with 126th Street are expected to increase by 275 to 650 vph during all seven peak hours, and volumes along West Park Loop/Stadium Road at the intersection with 126th Street can be expected to increase by approximately 175 to 975 vph per direction during the peak analysis hours.

Volumes along 126th Street in the vicinity of 34th Avenue can be expected to increase by approximately 300 to 1,050 vph per direction during non-game peak hours, and 500 to 675 vph during game day peak hours. In the vicinity of Roosevelt Avenue, 126th Street volumes can be expected to increase by about 335 to 710 vph per direction during non-game peak hours, and 400 to 525 vph per direction during game day peak hours.

College Point Boulevard volumes can be expected to increase by about 28 to 185 vph per direction during the peak analysis hours.

Volumes along 114th Street in the vicinity of Roosevelt Avenue can be expected to increase by approximately 65 to 450 vph in the northbound direction and 25 to 45 vph in the southbound direction during the peak analysis hours. Projected volume increments on the other north-south streets, including 108th Street, Main Street, Union Street, and Parsons Boulevard can be expected to be 65 vph per direction or less during the peak analysis hours.

The remainder of this section provides an overview of significant traffic impacts that would be generated under 2032 full buildout With Action conditions. Detailed volume-to-capacity (v/c) ratios, average vehicle delay, and levels of service movement-by-movement at each intersection under the 2032 With Action condition are provided at the end of this chapter. Project-generated traffic volume increment maps and total With Action volume maps are provided in **Appendix C**.

Levels of service for the 2032 With Action condition were determined for 29 of the 31 intersections (both signalized and unsignalized) analyzed under the No Action condition. Two unsignalized intersections, Willets Point Boulevard at 126th Street and Boat Basin Road at Stadium Road, analyzed under the No Action condition, would be eliminated due to street demapping and intersection improvements, and two new signalized intersections, 126th Street at New Willets Point Boulevard and CitiField/Lot B Internal Street at Roosevelt Avenue, would be created as part of the proposed project under Phase 2. Future traffic levels of service under the With Action condition are shown in **Tables 14-55 through 14-58**.

Table 14-55

Overall Intersection Level of Service Summary Comparison
Phase 2 (2032) No Action vs. With Action Conditions—Non-Game Day

Signalized Intersections	Phase 2 No Action Condition				Phase 2 With Action Condition			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				28 30 Signalized Intersections			
Overall Intersection LOS A/B/C	11	15	12 11	14	9 11	8	6 8	6 8
Overall Intersection LOS D	7	4	5 7	2	6 5	3 5	5	4 3
Overall Intersection LOS E	7	3	7 6	7	4 5	5 4	2 1	5
Overall Intersection LOS F	1	4	2	3	9	12 13	15 16	13 14
No. of Locations with Significant Impacts	--	--	--	--	20 22	23 25	23 25	23 24
Note: During the non-game peak hours in the Phase 2 With Action condition, <u>two one</u> of the three <u>four</u> unsignalized intersections analyzed would be significantly impacted in the weekday AM peak hour, and all three <u>four</u> unsignalized intersections would be impacted during the weekday midday and PM peak hours, and <u>three unsignalized intersections would be impacted</u> during the <u>weekday and</u> Saturday midday peak hours.								

Table 14-56

Traffic Lane Group Level of Service Summary Comparison
Phase 2 (2032) No Action vs. With Action Conditions—Non-Game Day

Signalized Movements	Phase 2 No Action Condition				Phase 2 With Action Condition			
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday
	26 Signalized Intersections				28 30 Signalized Intersections			
No. of Lane Groups at LOS A/B/C	56	72 74	57 58	69 70	58 63	57 60	47 51	55 59
No. of Lane Groups at LOS D	38 41	30 31	38 39	24 27	33 39	26 30	36 41	21 25
No. of Lane Groups at LOS E	13	10 9	9 11	16 15	11 10	17 18	12 11	17 18
No. of Lane Groups at LOS F	22	18 19	25 24	21	37 39	43 48	47 52	54 54
Note: During the non-game peak hours in the Phase 2 With Action conditions, <u>two one</u> of the ten <u>eleven</u> unsignalized lane groups analyzed would operate at LOS F in the weekday AM peak hour, and five lane groups would operate at LOS F during the weekday midday, weekday PM, and Saturday midday peak hours, and <u>one lane group would operate at LOS E and five lane groups would operate at LOS F during the weekday PM peak hour</u> . One lane group would operate at LOS D during the weekday AM and Saturday midday peak hours, and all other movements would operate at LOS C or better during all peak hours.								

Table 14-57

Overall Intersection Level of Service Summary Comparison
Phase 2 (2032) No Action vs. With Action Conditions—Game Day

Signalized Intersections	Phase 2 No Action Condition			Phase 2 With Action Condition		
	Weekday Pre-game	Weekend Pre-game	Weekend Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			28 30 Signalized Intersections		
Overall Intersection LOS A/B/C	8 7	12	10	7 6	8	7
Overall Intersection LOS D	10 11	2	2	4 6	7 6	3
Overall Intersection LOS E	5 4	7	7	4 5	1	2 4

No. of Locations with Significant Impacts	--	--	--	22 24	20 22	20 22
Note: During the game day peak hours in the Phase 2 With Action condition, all three <u>four</u> unsignalized intersections analyzed would be significantly impacted in-game day during the <u>weekday pre-game</u> peak hours, and <u>three unsignalized intersections would be significantly impacted during the Saturday pre- and post-game peak hours</u> .						

Table 14-58

Traffic Lane Group Level of Service Summary Comparison
Phase 2 (2032) No Action vs. With Action Conditions—Game Day

Signalized Movements	Phase 2 No Action Condition			Phase 2 With Action Condition		
	Weekday Pre-game	Weekend Pre-game	Weekend Post-game	Weekday Pre-game	Saturday Pre-game	Saturday Post-game
	26 Signalized Intersections			28 30 Signalized Intersections		
No. of Lane Groups at LOS A/B/C	57	64 66	69 70	48 51	54 57	58 60
No. of Lane Groups at LOS D	34 36	28 29	23 26	32 35	27 28	25 28
No. of Lane Groups at LOS E	46 17	7	6 5	43 14	44 18	6 10
No. of Lane Groups at LOS F	23	31	32	47 50	44 46	51 53

Note: During the game day peak hours in the Phase 2 With Action conditions, six of the ~~ten~~ eleven unsignalized lane groups analyzed would operate at LOS F during the weekday and Saturday pre-game peak hours. Five of the ~~ten~~ eleven unsignalized lane groups would operate at LOS F during the Saturday post-game peak hour. One unsignalized lane group would operate at LOS D during the weekday pre-game and Saturday post-game peak hours. All other unsignalized lane groups would operate at LOS C or better during game day peak hours.

The addition of the proposed project's generated traffic under full buildout conditions to the already poor future baseline (2032 No Action) conditions would cause the majority of locations to be significantly impacted. During non-game peak hours, full buildout of the proposed project would have significant traffic impacts at ~~20 22~~ 22 of the ~~28 30~~ 28 30 signalized intersections analyzed in the weekday AM peak hour, ~~and 23 25~~ 23 25 of ~~28 30~~ 28 30 in the weekday midday, ~~and~~ and weekday PM peak hours, and ~~24 of 30 in the~~ 24 of 30 in the Saturday midday peak hours. During the weekday pre-game peak hour, ~~22 24~~ 22 24 of ~~28 30~~ 28 30 signalized intersections analyzed would have significant traffic impacts, and during the Saturday pre-game and post-game peak hours ~~20 22~~ 20 22 of ~~28 30~~ 28 30 signalized intersections analyzed would have significant impacts. ~~Two of the three unsignalized intersections analyzed would be significantly impacted during the weekday AM peak hour, and all three unsignalized intersections would be impacted during the other six peak analysis hours.~~ One of the four unsignalized intersections analyzed would have significant impacts during the weekday AM peak hour, all four unsignalized intersections would have significant impacts during the weekday PM and weekday pre-game peak hours, and three of the four unsignalized intersections would be impacted during the other four peak analysis hours.

The summary overview of the Phase 2 With Action condition without a Mets game indicates that:

- In the weekday AM peak hour, ~~43 14~~ 43 14 of the ~~28 30~~ 28 30 analyzed signalized intersections are projected to operate at overall LOS E or F, which is ~~five~~ six more than under the No Action condition (Note: there would be ~~two~~ four more intersections in the Phase 2 With Action condition as compared to the No Action condition). ~~Twenty~~ Twenty-two signalized intersections would be significantly impacted. The number of traffic lane groups that are expected to operate at LOS E or F would increase from 35 to ~~48~~ 49.
- In the weekday midday peak hour, the number of signalized intersections that would operate at overall LOS E or F would increase from seven under the No Action condition to 17 under the With Action condition, and there would be significant impacts at ~~23 25~~ 23 25 of the ~~28 30~~ 28 30 signalized intersections. The number of individual lane groups that would operate at LOS E or F would increase from 28 to ~~60~~ 66.
- In the weekday PM peak hour, the number of intersections that are projected to operate at overall LOS E or F would increase from ~~9~~ 8 to 17 under the With Action condition, with ~~23 25~~ 23 25 signalized intersections significantly impacted. The number of individual lane groups that would operate at LOS E or F would increase from ~~34 35~~ 34 35 to ~~59~~ 63.
- In the Saturday midday peak hour, the number of signalized intersections projected to operate at LOS E or F would increase from 10 under the No Action condition to ~~48~~ 19 under

the With Action condition. ~~Twenty-three~~ Twenty-four signalized intersections would be significantly impacted. The number of lane groups at LOS E or F would increase from ~~37~~ 36 to ~~68~~ 72.

- ~~All three~~ Three of the four unsignalized intersections would operate at overall LOS F and would be significantly impacted during all four non-game peak hours with the exception of the Grand Central Parkway exit ramp at West Park Loop/Stadium Road and Willeys Point Boulevard at Northern Boulevard, both of which would operate at LOS C during the weekday AM peak hour and would not be significantly impacted. The fourth unsignalized intersection would operate at LOS E during the weekday PM peak hour and would be significantly impacted. ~~Two~~ One of the ~~ten~~ eleven unsignalized lane groups analyzed would operate at LOS F in the weekday AM peak hour and five lane groups would operate at LOS F during the weekday midday, ~~weekday PM,~~ and Saturday midday peak hours. One unsignalized lane group would operate at LOS E and five lane groups would operate at LOS F during the weekday PM peak hour. Additionally, one intersection that was unsignalized in the No Action condition would be significantly impacted as a signalized intersection in the With Action condition during all non-game peak hours and one would be impacted during the weekday midday and PM peak hours.

The summary overview of the Phase 2 With Action condition with a Mets game indicates that:

- In the weekday PM pre-game peak hour, ~~17~~ 18 out of ~~28~~ 30 signalized intersections would operate at LOS E or F under the With Action condition, which is an increase from eight signalized intersections at LOS E or F under the No Action condition. There would be significant impacts at ~~22~~ 24 of the ~~28~~ 30 signalized intersections. The number of lane groups that would operate at LOS E or F would increase from ~~39~~ 40 to ~~60~~ 64.
- During the Saturday midday pre-game peak hour, the number of intersections that are expected to operate at LOS E or F would increase from 12 to ~~13~~ 16 under the With Action condition, with ~~20~~ 22 signalized intersections significantly impacted. The number of lane groups at LOS E or F would increase from 38 to ~~58~~ 64.
- In the Saturday PM post-game peak hour, the number of locations that would operate at LOS E or F would increase from 14 to ~~18~~ 20 under the With Action condition. ~~Twenty~~ Twenty-two signalized intersections would be significantly impacted. The number of lane groups that would operate at LOS E or F would increase from ~~38~~ 37 to ~~57~~ 63.
- ~~All three~~ Three of the four unsignalized intersections would operate at overall LOS F and would be significantly impacted during all gameday peak hours. The fourth unsignalized intersection would operate at LOS D and would be significantly impacted during the weekday pre-game peak hour. Six of the ~~ten~~ eleven unsignalized lane groups analyzed would operate at LOS F during the weekday and Saturday pre-game peak hours and five of the ~~ten~~ eleven unsignalized lane groups would operate at LOS F during the Saturday post-game peak hour. Additionally, two intersections that were unsignalized in the No Action condition would be significantly impacted as signalized intersections in the With Action condition during all game peak hours.

Table 14-59 shows the locations and time periods where significant impacts would occur in the Phase 2 (2032) With Action condition. Mitigation measures for significantly impacted locations are discussed in Chapter 21, ~~“Mitigation.”~~

Table 14-59

Phase 2 (2032) With Action Condition Significant Impact Summary

Intersections	Without a Mets Game				With a Mets Game		
	Weekday AM	Weekday Midday	Weekday PM	Saturday Midday	Pre-game Weekday PM	Pre-game Saturday Midday	Post-game Saturday PM

Northern Boulevard at 126th Place			x		x		
126th Street at 36th Avenue	x	x	x	x	x	x	x
126th Street at 37th Avenue		x	x		x	x	x

Notes: "x" means the intersection would be significantly impacted. n/a means the intersection is new for With Action conditions.

PHASE 2 (2032) WITH ACTION PARKING

Under Phase 2, the remainder of the District would be built out. The number of parking spaces provided under the full buildout would be based on project demand. It is anticipated that sufficient off-street and on-street parking would be provided to satisfy these demands under the full buildout. As detailed street configurations and curbside parking regulations have not yet been defined for existing and new streets within the District, it is expected that some level of on-street parking would be available. The proposed regulations would be designed to satisfy the needs of adjacent land uses; metered parking would likely be installed adjacent to retail uses or other commercial buildings, alternate side regulations would likely be installed near residential uses, and curbside parking restrictions would likely be imposed near the convention center, hotel, community facilities, or along primary delivery routes. Specific regulations would be determined at a later date.

Parking demand for the proposed residential component would be satisfied through on-street and off-street parking opportunities. As in the 2008 FGEIS, it is assumed that approximately 10 percent of residents would use available on-street parking opportunities, which would reduce the need for

off-street parking demand by about 300 spaces. Given the anticipated residential demand of 3,101 spaces, approximately 2,800 off-street residential parking spaces would need to be provided. Residential parking demand is typically lowest during the daytime hours when office, community uses, and primary school parking demands are at a maximum. Therefore, shared parking strategies would be implemented and, where possible, office, community, and primary school parking demands would use parking spaces vacated by residents during the daytime hours. This would maximize usage of vacant residential parking spaces during daytime hours and minimize the need for additional dedicated parking spaces for office, community, and primary school uses.

It is expected that the remaining land uses—retail, hotel, and convention center space—could also share common parking areas. However, because peaking patterns among these uses are similar to each other, there would be minimal savings in the number of required parking spaces. Hence, the projected weekday and Saturday parking demands for these uses are based on the sum of the individual peak demands, or approximately 3,050 spaces and 2,900 spaces, respectively. These accumulations by land use are detailed in **Tables 14-60** and **14-61**. The parking supply in the District would be provided to accommodate the highest demand, 3,047 spaces, which would be expected to occur on a weekday. Since parking areas designated for the retail, hotel, and convention center would likely be underutilized during the weekday, shared parking strategies could again be implemented and these parking facilities could also be used to accommodate office, community, and primary school parking demands, and further reduce the overall parking demand. In total, 5,850 parking spaces would be provided in the full buildout under Phase 2.

As detailed in the Phase 1A and Phase 1B Parking sections, parking provided for the Willets West development would fully satisfy its demand.

The CitiField Lot B development project is anticipated to be in place in Phase 2. The existing VIP/ADA parking spaces on Lot B are assumed to be replaced on site; however, accessory parking for the Lot B development is anticipated to be satisfied within a new parking structure on Lot D, located on the south side of Roosevelt Avenue. **Table 14-62** shows the projected parking accumulation by hour for the proposed Lot B development on a weekday and on a Saturday, and indicates a peak parking demand of 648 spaces on a weekday and 389 spaces on Saturday. Most of the weekday demand would be generated by office space and overall parking demand would decrease to less than 200 spaces by the 5-6 PM hour when Mets game attendees would begin to arrive. Within the footprint of the new South Lot/Lot D structures, a total of 5,495 spaces would be constructed, which would provide Mets parking and would continue to accommodate existing usage. Based on game day parking occupancy rates under the No Action conditions, there would be enough available parking spaces to also satisfy all of Lot B's parking demand.

G. HIGHWAY NETWORK ANALYSIS

INTRODUCTION AND METHODOLOGY

Because of the proximity of the project site to the regional highway network through north-central Queens, analyses were performed to assess the potential for significant adverse impacts on the Grand Central Parkway, the Van Wyck/Whitestone Expressway (both designated as I-678), and the ramps connecting the highways to the local street network. The highway analyses include the following locations:

- Grand Central Parkway mainline in both directions between the LIE and Roosevelt Avenue
- Van Wyck Expressway mainline in both directions between the LIE and Roosevelt Avenue
- Whitestone Expressway mainline in both directions between Northern Boulevard and Linden Place
- Ramp from World's Fair Marina/Boat Basin Road to the Grand Central Parkway
- Ramps from the northbound Van Wyck Expressway to eastbound and westbound Northern Boulevard
- Ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway
- Ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway
- Ramp from eastbound Astoria Boulevard and eastbound Northern Boulevard to the northbound Whitestone Expressway

Willeys Point Development

- Ramps from the southbound Whitestone Expressway to the eastbound and westbound Grand Central Parkway
- Ramp from westbound Northern Boulevard and southbound Whitestone Expressway to westbound Astoria Boulevard
- Ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard
- Ramp from the eastbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway
- Ramp from the southbound Whitestone Expressway to westbound Northern Boulevard

The ramps from eastbound Northern Boulevard and the Grand Central Parkway to 126th Street as well as the combined ramp section from the northbound Van Wyck Expressway and southbound Whitestone Expressway to westbound Northern Boulevard at 126th Street are signalized approaches and, as such, are included in the intersection analyses instead of the highway analyses.

It is beyond the scope of the 2000 *HCM* to analyze a highway section that is operating at low speeds or over-saturated conditions. Therefore, a simulation of the highway network with the CORSIM model (Version 6.2) was used instead (as was done for the 2008 FGEIS and has been done on numerous recent EISs in New York City), because it better replicates existing and projected future conditions in the study area. The ability to account for traffic conditions that influence the immediate study area is critical when modeling traffic conditions on typical weekdays and, even more importantly, before and after Mets games at CitiField.

The CORSIM model reports the density and an average speed for the highway section being analyzed, but does not readily report the levels of service. Levels of service are necessary to assess potential impacts of the proposed development on the highway as per *CEQR Technical Manual* guidelines. The 2000 HCM defines levels of service thresholds for merge and diverge areas using density in passenger cars per mile per lane (pc/mi/ln), and these thresholds have been applied to the results of the CORSIM model. The levels of service thresholds for each density range are as follows:

- LOS A describes operations with very low densities (i.e., less than or equal to 10 pc/mi/ln) and high free flow speeds.
- LOS B describes operations with fairly low densities (i.e., greater than 10 to 20 pc/mi/ln) and moderate to high free flow speeds.
- LOS C describes operations with moderate densities (i.e., greater than 20 to 28 pc/mi/ln) and moderate free flow speeds.
- LOS D describes operations with moderate to high densities (i.e., greater than 28 to 35 pc/mi/ln) and moderate to low free flow speeds. A mid-LOS D density of 31.5 pc/mi/ln is considered the high range of acceptable density. Densities greater than 31.5 pc/mi/ln are unacceptable but are commonplace on highways in New York City.
- LOS E describes operations with high densities (i.e., greater than 35 pc/mi/ln) and low free flow speeds. 45 pc/mi/ln is considered the maximum density for sustained flows at capacity on a typical freeway. Queuing can begin at densities higher than this.
- LOS F describes operations with very high densities and very low free flow speeds. Queuing is common within LOS F, which leads to failure conditions and congestion.

According to the *CEQR Technical Manual*, for highway or ramp sections being analyzed—including mainline capacity sections, weaving areas, and ramp junctions—a significant adverse impact occurs when conditions deteriorate by more than half an LOS between No Action and With Action conditions when No Action LOS is in the D, E, or F range. The following significant impact criteria are used in the With Action analyses to assess potential impacts of the proposed development on the highway network:

- For No Action LOS D to With Action LOS D: Since the starting value of LOS D is 28 pc/mi/ln and the highest value of LOS D is 35 pc/mi/ln, one half of the difference between these two is 3.5 pc/mi/ln. Hence, an increase in the projected density of 4 pc/mi/ln or more as a result of traffic volume added between the No Action and With Action conditions is considered a significant impact.
- For No Action LOS D to With Action LOS E: Since the value of mid-LOS D is 31.5 pc/mi/ln and the starting value of LOS E is 35 pc/mi/ln, one half of the difference between these two is 1.75 pc/mi/ln. Therefore, an increase in the projected density of 2 pc/mi/ln or more between No Action and With Action is considered a significant impact.
- For No Action LOS E to With Action LOS F: The same criteria as No Action LOS D to With Action LOS E applies.

EXISTING CONDITIONS

GRAND CENTRAL PARKWAY VOLUMES

Traffic volumes on the eastbound Grand Central Parkway mainline approaching the diverge to the Whitestone Expressway and eastbound Northern Boulevard (designated as eastbound Exit 9E), range from 2,650–4,050 vph during typical non-game weekday AM, midday, PM and Saturday midday peak hours, and from 3,900–4,800 vph during game conditions. The ramp from the eastbound Grand Central Parkway to the Whitestone Expressway and eastbound Northern Boulevard, which is a major split toward the District from the eastbound mainline, carries approximately 2,250–3,750 vph during the non-game analysis periods and 2,750–4,400 vph during game periods. South of the diverge, the Grand Central Parkway receives approximately 450–800 vph from the ramp from the Whitestone Expressway and westbound Northern Boulevard during the non-game periods and 600–750 vph during the game periods. The next merge onto the eastbound mainline (from the 34th Avenue/114th Street intersection and from Astoria Boulevard) adds approximately 800–1,055 vph during the various analysis peak hours. Farther south along the eastbound Grand Central Parkway, between the Roosevelt Avenue overpass and the LIE, traffic volumes range 4,800–6,250 vph during the non-game analysis time periods, and 6,100–6,550 vph for game conditions.

Traffic volumes on the Grand Central Parkway westbound mainline just north of the ramps from the LIE range from 4,350–5,800 vph during typical non-game weekday AM, midday, PM and Saturday midday peak hours, and from 5,300–5,850 vph during game conditions. Farther north, the westbound mainline divides: traffic destined for the ramp to the Whitestone Expressway and eastbound Northern Boulevard (designated as westbound Exit 9E) as well as a portion of traffic that continues on the mainline through the study area take the east side of the highway; and traffic destined for the ramp to westbound Northern Boulevard (designated as westbound Exit 9W) as well as the remaining traffic that continues on the mainline through the study area take the west side of the highway. The east half of the mainline carries approximately 1,900–2,500 vph and 2,400–3,050 vph during the non-game and game peak hours, respectively. The west half of the mainline carries approximately 2,500–3,350 vph and 2,700–2,900 vph during the non-

game and game peak hours, respectively. The ramp to the Whitestone Expressway and eastbound Northern Boulevard (Exit 9E), which provides access to the vicinity of CitiField and the District from the westbound mainline, carries approximately 250–350 vph during the non-game analysis periods and 350–1,050 vph during game periods. The ramp to westbound Northern Boulevard (Exit 9W) carries approximately 700–1,150 vph during the non-game analysis periods and 700–1,250 vph during game periods. Farther north just prior to the point where the two segments of the westbound mainline rejoin, traffic entering the east half of the mainline from the combined ramp from the Whitestone Expressway and westbound Northern Boulevard as well as the World's Fair Marina/Boat Basin Road ranges from 2,000–2,450 vph and 1,450–2,500 vph during the non-game and game peak hours, respectively.

VAN WYCK / WHITESTONE EXPRESSWAY VOLUMES

The Van Wyck Expressway (I-678) northbound mainline, north of the LIE and the on-ramp from College Point Boulevard, is traveled by approximately 3,500–5,100 vph during typical non-game weekday AM, midday, PM and Saturday midday peak hours, and from 3,700–4,150 vph during game conditions. The northbound diverge toward Northern Boulevard (Exit 13) carries approximately 1,100–1,450 vph and 1,050–1,200 vph during the non-game and game analysis periods, respectively. Of the total volumes during all of the analysis peak hours, approximately 600–700 vph take Exit 13E toward Downtown Flushing, while 250–450 vph take Exit 13W toward westbound Northern Boulevard, the Grand Central Parkway and access to CitiField. North of the District, the continuation of I-678 northbound, the Whitestone Expressway, is traveled by approximately 4,350–6,900 vph and 5,350–7,150 vph during non-game and game analysis periods, respectively.

North of the District, the southbound Whitestone Expressway mainline splits, with one section of the highway continuing south as the Van Wyck Expressway and the other turning west toward the Grand Central Parkway. Upstream of this split, the Whitestone Expressway is traveled by approximately 3,900–5,700 vph and 4,000–5,500 vph during non-game and game analysis periods, respectively. In the vicinity of Northern Boulevard, the southbound mainline (now the Van Wyck Expressway) receives traffic from two ramps: the merge from westbound Northern Boulevard, which adds approximately 550–800 vph during the seven analysis peak hours; and the merge with the ramp from the northbound Whitestone Expressway (with the combined traffic entering from the Grand Central Parkway, eastbound Northern Boulevard, and Astoria Boulevard), which totals approximately 450–950 vph during all of the peak hours. The Van Wyck Expressway southbound mainline, north of the exit to College Point Boulevard (Exit 12A), carries approximately 2,750–3,650 vph during typical non-game weekday AM, midday, PM and Saturday midday peak hours, and from 3,250–3,700 vph during game conditions.

EXISTING LEVELS OF SERVICE

NON-GAME DAY CONDITIONS

Table 14-63 presents existing speeds, densities, and levels of service for 19 segments of the mainlines or ramps of the highway network analyzed for typical non-game-day peak hours. Average travel speeds on the highway mainlines are generally between 35 and 50 miles per hour (mph) during the AM peak hour, except for the southbound Whitestone Expressway, which has an average travel speed of approximately 27 mph. Average travel speeds on the highway mainlines during the weekday midday, PM, and Saturday midday peak hours generally range from 32 to 46 mph.

Table 14-63

Note: "n/a" signifies not available												

For the highway mainline sections, unacceptable LOS E or F conditions occur along the eastbound and west side of the westbound Grand Central Parkway mainline split, northbound Van Wyck Expressway, and southbound Whitestone Expressway during the AM peak hour, and along the eastbound Grand Central Parkway, northbound Van Wyck Expressway, and northbound Whitestone Expressway during the PM peak hour. The other mainline sections generally operate at LOS B, C, or D during the weekday AM and PM peak hours. During the weekday midday peak hours, all analyzed highway mainline sections operate at acceptable LOS B, C or D. During the Saturday midday peak hour, the eastbound and west side of the westbound Grand Central Parkway mainline split generally operates at unacceptable LOS E; the other mainline sections generally operate at a LOS C or D.

The ramp from the southbound Whitestone Expressway to the westbound Grand Central Parkway operates at unacceptable LOS D during the weekday PM peak hour. All other ramps operate at acceptable levels of service during all non-game day peak hours.

GAME DAY CONDITIONS

Table 14-64 presents existing speeds, densities, and levels of service for the 19 sections or ramps of the highway network during the game-day peak hours. Pre-game traffic to CitiField on the highways primarily uses the southbound Whitestone Expressway, taking the exit to westbound Northern Boulevard; the eastbound Grand Central Parkway, taking the exit to 126th Street; and the westbound Grand Central Parkway, taking the exit to Stadium Road and the exit to 126th Street. These exit ramps frequently spill back onto the highway mainlines during the pre-game peak hours, causing additional slowdown for through (non-exiting) traffic. Departing traffic during the post-game peak hour accesses the northbound Whitestone Expressway, southbound Van Wyck Expressway, and the westbound Grand Central Parkway from the entrance ramps from Stadium Road; exiting game traffic also accesses the westbound Grand Central Parkway via the entrance ramp from World's Fair Marina/Boat Basin Road. Exiting game traffic to the eastbound Grand Central Parkway uses the entrance ramp from 114th Street and the entrance ramp farther south from Flushing Meadow Park internal roads (United Nations Avenue and Avenue of Science).

Weekday PM and weekend midday pre-game average travel speeds on the highway mainlines generally range between approximately 35 and 47 mph except for the southbound Whitestone Expressway whose travel speed is approximately 13 mph during the weekday PM pre-game peak hour, due to spillback from the exit ramp to westbound Northern Boulevard. That ramp operates with a travel speed of about 6 mph during the weekday PM pre-game peak hour.

Pre-game highway traffic toward CitiField and its surrounding lots causes unacceptable LOS E or F conditions on the northbound and southbound Whitestone Expressway mainline during the weekday pre-game peak hour. The eastbound and west side of the westbound Grand Central Parkway mainline split, and northbound Van Wyck Expressway operate at unacceptable LOS D or E during both the weekday PM and Saturday midday pre-game peak hours. The other highway mainlines generally operate at LOS C and acceptable D during the pre-game peak hours.

The Saturday post-game highway conditions are the most congested of all the time periods due to the surge of game traffic from the parking lots onto the adjacent streets and onto the ramps and highway mainlines. As a result, post-game peak hour average travel speeds generally range between 23 and 47 mph. The eastbound and west side of the westbound Grand Central Parkway mainline split as well as the northbound Van Wyck Expressway and northbound Whitestone Expressway experience unacceptable LOS D, E or F conditions. The southbound Van Wyck Expressway and the southbound Whitestone Expressway operate at LOS C.

The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard experiences LOS E/F conditions during the weekday and Saturday pre-game periods. All other ramp locations operate at acceptable levels of service during the pre-game and post-game peak hours.

THE FUTURE WITHOUT THE PROPOSED PROJECT

This section details the expected traffic volume increases, levels of service, density and speeds along the highway network for each year of buildout: Phase 1A in 2018; Phase 1B in 2028; and Phase 2 in 2032. Overall, highway conditions generally deteriorated or remained the same under the Phase 1A, Phase 1B and Phase 2 No Action conditions as compared to existing conditions; however, in some instances, speeds and levels of service improved slightly between the existing and No Action conditions due to saturation of one analyzed mainline or ramp, which causes a metering of vehicles arriving at (and consequential improvement of) downstream analysis locations. Signal phasing and timing changes proposed by NYCDOT at the intersection of Northern Boulevard and 126th Street were incorporated in the Final SEIS analysis.

PHASE 1A (2018) NO ACTION CONDITION

Traffic volumes on the analyzed sections of the highway network are expected to increase by a background growth rate of 0.5 percent per year for the first five years (between 2012 and 2017) and 0.25 percent per year for every year beyond that (between 2017 and 2018), plus traffic expected to be generated by other projected No Action development projects. In the Phase 1A No Action condition, traffic volumes along the Grand Central Parkway eastbound mainline would increase by about 250 to 375 vph. In the westbound direction along the Grand Central Parkway, volumes would increase by approximately 110 to 150 vph on the east side split and by 110 to 135 vph on the west side split. Traffic volumes along the northbound mainline of the Van Wyck Expressway would increase by 260 to 315 vph, and by 200 to 320 vph along the southbound mainline. Traffic volumes along the Whitestone Expressway would increase by 135 to 210 vph in the northbound direction and by 125 to 165 vph in the southbound direction.

HIGHWAY LEVELS OF SERVICE

Under the Phase 1A No Action conditions, increased vehicular volumes would result in higher densities and lower speeds on several ramps and highway sections. In a few instances, conditions improved slightly between existing and Phase 1A No Action conditions. This is primarily a result of congested ramps and merges having a “metering” effect on adjacent downstream segments of the highway network.

Non-Game Day

Table 14-65 presents the projected No Action Phase 1A levels of service, speeds, and densities for the 19 sections of the highway network analyzed during the non-game day peak hours.

Mainlines

The eastbound Grand Central Parkway mainline would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday midday peak hour and would deteriorate from an unacceptable LOS E to unacceptable LOS F in the weekday PM peak hour, and would continue to operate with average speeds of approximately 33 to 37 mph. The west side of the westbound Grand Central Parkway mainline split would deteriorate from an acceptable LOS D to an unacceptable LOS D during the weekday PM peak hour and would continue to operate with average speeds of approximately 45 mph.

The northbound Van Wyck Expressway mainline would deteriorate from unacceptable LOS E to unacceptable LOS F during the weekday AM peak hour, and would deteriorate from an unacceptable LOS D to unacceptable LOS E during the Saturday midday peak hour, but would continue to operate with similar average speeds as under existing conditions during all time periods. The southbound Van Wyck Expressway mainline would deteriorate from an acceptable LOS D to an unacceptable LOS D during the weekday PM peak hour and would ~~deteriorate in average speed from 39 mph to 36~~ continue to operate with an average speed of approximately 39 mph. The southbound Whitestone Expressway mainline would deteriorate from LOS E to LOS F during the weekday AM peak hour but would continue to operate with average speeds around ~~27~~ 26 mph.

Ramps

The ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from acceptable LOS C to unacceptable LOS D during the weekday AM and midday peak hours and from LOS C to LOS E during the Saturday midday peak hour. The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday AM peak hour. The ramp from the southbound Whitestone Expressway to the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to unacceptable LOS D during the Saturday midday peak hour. However, none of these ramps would experience a drop in average speed. The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to an unacceptable LOS F during the weekday AM peak hour and would experience a drop in average speed from approximately 23 mph to ~~13~~ 15 mph.

Game Day

The Phase 1A No Action levels of service, speeds, and densities for the analyzed sections during the game day peak hours are shown in **Table 14-66** and are summarized below.

Mainlines

The eastbound Grand Central Parkway would continue to operate at unacceptable LOS E or F during all peak hours with similar speeds. The east side of the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to an unacceptable LOS ~~F~~ D during the Saturday pre-game peak hour and would ~~incur a drop in average travel speed from~~ continue to operate at approximately 36 mph to 19 mph. The northbound Van Wyck Expressway would deteriorate from an unacceptable LOS D to an unacceptable LOS E in both the weekday pre-game and Saturday post-game peak hours but would continue to operate with similar travel speeds. The southbound Van Wyck Expressway would deteriorate from an acceptable LOS D to an unacceptable LOS E during the weekday pre-game peak hour and would incur a drop in average travel speed from 38 mph to 33 mph. The northbound Whitestone Expressway would deteriorate from an unacceptable LOS E to unacceptable LOS F during the weekday pre-game peak hour and would deteriorate from an acceptable LOS C to unacceptable LOS D in the Saturday pre-game peak hour, and would continue to operate with average speeds of 39 to 40 mph. The rest of the mainline segments would operate at similar levels of service to existing conditions.

Ramps

The ramp from northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from LOS C to LOS D during the Saturday pre-game and post-game peak hours but would maintain similar average travel speeds. Along the ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway, levels of service would deteriorate from LOS D to LOS E during the Saturday pre-game peak hour yet travel speeds would remain similar to existing conditions. The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway/eastbound Northern Boulevard would deteriorate from LOS C to LOS F during the weekday pre-game and Saturday pre-game peak hours. The ramp from the westbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway would ~~deteriorate from LOS B to LOS F during the Saturday pre-game peak hour and travel speeds would drop correspondingly from an average of approximately 44 mph to 5 mph.~~ operate at similar levels of service to existing conditions. The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would deteriorate from LOS E to LOS F during the Saturday pre-game peak hour and would experience a reduction in average travel speed from 26 mph to ~~16~~ 21 mph.

PHASE 1B (2028) NO ACTION CONDITION

Traffic volumes on the analyzed sections of the highway network are expected to increase by a background growth rate of 0.5 percent per year for the first five years (between 2012 and 2017) and 0.25 percent per year for every year beyond that (between 2017 and 2028), plus traffic expected to be generated by other projected No Action development projects. In the Phase 1B No Action condition, traffic volumes along the Grand Central Parkway eastbound mainline

would increase by about 425 to 640 vph. In the westbound direction along the Grand Central Parkway, volumes would increase by approximately 170 to 230 vph on the east side split and by 185 to 225 vph on the west side split. Traffic volumes along the northbound mainline of the Van Wyck Expressway would increase by 355 to 435 vph, and by 275 to 415 vph along the southbound mainline. Traffic volumes along the Whitestone Expressway would increase by 245 to 390 vph in the northbound direction and by 225 to 305 vph in the southbound direction.

HIGHWAY LEVELS OF SERVICE

Under the Phase 1B No Action conditions, increased vehicular volumes would result in higher densities and lower speeds on several ramps and highway sections. In a few instances, conditions improved slightly between existing and Phase 1B No Action conditions. This is primarily a result of congested ramps and merges having a “metering” effect on adjacent downstream segments of the highway network.

Non-Game Day

Table 14-67 presents the projected No Action Phase 1B levels of service, speeds, and densities for the 19 sections of the highway network analyzed during the non-game day peak hours.

Mainlines

The eastbound Grand Central Parkway mainline would deteriorate from an acceptable LOS D to unacceptable LOS ~~E~~ D during the weekday midday peak hour and would deteriorate from an unacceptable LOS E to unacceptable LOS F in the weekday PM peak hour, and would continue to operate with average speeds of 33 to 37 mph. The west side of the westbound Grand Central Parkway mainline split would deteriorate from an acceptable LOS D to an unacceptable LOS D during the weekday PM peak hour and would continue to operate with average speeds of approximately 45 mph. This segment would continue to operate at LOS E during the Saturday midday peak hour and maintain a similar average speed.

The northbound Van Wyck Expressway mainline would deteriorate from unacceptable LOS E to unacceptable LOS F during the weekday AM peak hour dropping slightly in average speed from 35 mph to 34 mph, and would also deteriorate from an unacceptable LOS D to unacceptable LOS E during the Saturday midday peak hour, but would continue to operate with similar average speeds as under existing conditions during all time periods. The southbound Van Wyck Expressway mainline would deteriorate from an acceptable LOS D to unacceptable LOS ~~D~~ F during the weekday PM peak hour and average speeds would continue to operate with average speeds of approximately ~~deteriorate from 39 mph to 25 mph.~~ This segment would also deteriorate from an acceptable LOS C to an unacceptable LOS D during the Saturday midday peak hour with average speeds that would deteriorate from 41 mph to 38 mph.

The southbound Whitestone Expressway mainline would deteriorate from LOS E to LOS F during the weekday AM peak hour and from LOS D to LOS E during the ~~Saturday midday~~ weekday PM peak hour but would continue to operate with similar average speeds as in existing conditions.

Ramps

The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday AM peak hour. The ramp from the southbound Whitestone Expressway to the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday AM and Saturday midday peak hours. However, these ramps would not experience a

Willetts Point Development

drop in average speed. The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to an unacceptable LOS F during the weekday AM peak hour and would experience a drop in average speed from approximately 23 mph to 40 6 mph.

Game Day

The Phase 1B No Action levels of service, speeds, and densities for the analyzed sections during the game day peak hours are shown in **Table 14-68** and are summarized below.

Table 14-68

Mainlines

The eastbound Grand Central Parkway would continue to operate at unacceptable LOS E or F during all peak hours with similar speeds. The east side of the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to an unacceptable LOS ~~F~~ D during the Saturday pre-game peak hour ~~and would incur a drop in average travel speed from 36 mph to 16 mph, but would continue to operate with a similar average speed as in existing conditions.~~ The northbound Van Wyck Expressway would deteriorate from an unacceptable LOS D to an unacceptable LOS E in both the weekday pre-game and Saturday post-game peak hours but would continue to operate with similar travel speeds, while the southbound Van Wyck Expressway would deteriorate from LOS D to LOS ~~F~~ E during the weekday pre-game peak hour and would experience a drop in average travel speed from approximately 38 mph to ~~23~~ 34 mph. The northbound Whitestone Expressway would deteriorate from an acceptable LOS C to an unacceptable LOS D during the Saturday pre-game peak hour but would continue to operate with a similar average speed as in existing conditions. The rest of the mainline segments would operate at similar levels of service to existing conditions.

Ramps

The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway/eastbound Northern Boulevard would deteriorate from LOS C to LOS F during the weekday and Saturday pre-game peak hours and would experience a drop in average speeds from 35-38 mph to ~~5-6~~ 6-11 mph. ~~The ramp from the westbound Grand Central Parkway towards Stadium Road and the northbound Whitestone Expressway would deteriorate from LOS B to LOS F during the Saturday pre-game peak hour and would experience a corresponding reduction in average travel speed from 44 mph to 3 mph.~~ The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the weekday pre-game peak hour, and would deteriorate from LOS E to LOS F in the Saturday pre-game peak hour where it would also experience a drop in average travel speed from about 26 mph to ~~14~~ 17 mph.

PHASE 2 (2032) NO ACTION CONDITION

Traffic volumes on the analyzed sections of the highway network are expected to increase by a background growth rate of 0.5 percent per year for the first five years (between 2012 and 2017) and 0.25 percent per year for every year beyond that (between 2017 and 2032), or approximately 6.5 percent overall, plus traffic expected to be generated by other projected No Action development projects. In the Phase 2 No Action condition, traffic volumes along the Grand Central Parkway eastbound mainline would increase by about 460 to 600 vph. In the westbound direction along the Grand Central Parkway, volumes would increase by approximately 195 to 260 vph on the east side split and by 210 to 260 vph on the west side split. Traffic volumes along the northbound mainline of the Van Wyck Expressway would increase by 265 to 490 vph, and by 225 to 410 vph along the southbound mainline. Traffic volumes along the Whitestone Expressway would increase by 150 to 470 vph in the northbound direction and by 250 to 375 vph in the southbound direction.

HIGHWAY LEVELS OF SERVICE

Under the Phase 2 No Action conditions, increased vehicular volumes would result in higher densities and lower speeds on several ramps and highway sections. In a few instances, conditions improved slightly between existing and Phase 2 No Action conditions. This is primarily a result of congested ramps and merges having a “metering” effect on adjacent downstream segments of the highway network.

Non-Game Day

Table 14-69 presents the projected No Action Phase 2 levels of service, speeds, and densities for the 19 sections of the highway network analyzed during the non-game day peak hours.

Mainlines

The eastbound Grand Central Parkway mainline would deteriorate from an acceptable LOS D to unacceptable LOS E during the weekday midday peak hour ~~and would deteriorate from an unacceptable LOS E to unacceptable LOS F in the weekday PM peak hour~~, and would continue to operate with an average speeds of ~~33 to~~ 37 mph. The west side of the westbound Grand Central Parkway mainline split would deteriorate from an acceptable LOS D to an unacceptable LOS D during the weekday PM peak hour and would continue to operate with average speeds of approximately ~~45~~ 44 mph. This segment would continue to operate at LOS E during the Saturday midday peak hour and maintain a similar average speed as for existing conditions.

The northbound Van Wyck Expressway mainline would deteriorate from unacceptable LOS E to unacceptable LOS F during the weekday AM peak hour dropping slightly in average speed from 35 mph to 34 mph. The southbound Van Wyck Expressway mainline would deteriorate from an acceptable LOS D to LOS F during the weekday PM peak hour and would deteriorate in average speed from 39 mph to ~~47~~ 11 mph, and from LOS C to LOS E during the Saturday midday peak hour with a drop in average speed from about 41 mph to ~~32~~ 29 mph.

The southbound Whitestone Expressway mainline would deteriorate from LOS E to LOS F during the weekday AM peak hour and from LOS D to LOS E during the ~~Saturday midday~~ weekday PM peak hour but would continue to operate with similar average speeds as in existing conditions.

Ramps

The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday AM peak hour. The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS B to LOS ~~E~~ F during the weekday PM peak hour and would drop in average speed from approximately 40 mph to ~~20~~ 9 mph. The ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway would deteriorate from LOS C to LOS ~~E~~ F during the weekday PM peak hour and would experience a drop in average speed, from 29 mph to ~~45~~ 6 mph. The ramp from the southbound Whitestone Expressway to the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to unacceptable LOS D during the weekday AM, weekday PM and Saturday midday peak hours. However, these ramps would not experience a drop in average speed. The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would deteriorate from an acceptable LOS D to an unacceptable LOS F during the weekday AM peak hour and would experience a drop in average speed, from approximately 23 mph to ~~6~~ 9 mph.

In a few instances, conditions improved slightly between existing and Phase 2 No Action. This is primarily a result of congested ramps and merges having a “metering” effect on adjacent downstream segments of the highway network.

Game Day

The Phase 2 No Action levels of service, speeds, and densities for the analyzed sections during the game day peak hours are shown in **Table 14-70** and are summarized below.

Mainlines

The east side of the westbound Grand Central Parkway would deteriorate from an acceptable LOS D to an unacceptable LOS ~~F~~ D during the Saturday pre-game peak hour ~~and would incur a drop in average travel speed from 36 mph to 3 mph but would continue to operate with a similar average speed as in existing conditions~~, and the west side of the westbound Grand Central Parkway would deteriorate from unacceptable LOS D during both the Saturday pre- and post-game peak hours to LOS ~~F~~ E during the Saturday pre-game ~~peak hour and LOS E during the Saturday and~~ post-game peak hours. The average travel speeds would ~~reduce from approximately~~ maintain the same average speed of 44 mph as in the existing conditions during to 39 mph in the Saturday pre-game peak hour and would decrease from 44 to 43 mph in the post-game peak hour. The northbound Van Wyck Expressway would deteriorate from an unacceptable LOS D to an unacceptable LOS ~~F~~ E during the weekday pre-game peak hour and would maintain the same average speed of ~~drop in average speed from 38 mph to 22 mph as in the existing conditions~~. This segment would also deteriorate from LOS D to LOS E in the Saturday post-game peak hour but would maintain similar average speeds to existing conditions. The southbound Van Wyck Expressway would deteriorate from acceptable LOS D to unacceptable LOS D during the weekday pre-game peak hour and would ~~experience a drop in average travel speed from approximately 38 mph to 32 mph. continue to operate with a similar average speed as existing conditions~~. The rest of the mainline segments would operate at similar levels of service to existing conditions.

Ramps

~~The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from LOS B to LOS F during the weekday pre game peak hour and would experience a drop in average speed from approximately 25 mph to 4 mph. The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway/eastbound Northern Boulevard would deteriorate from LOS C to LOS F during the weekday and Saturday pre-game peak hours and would experience a drop in average speeds from 35-38 mph to 4-5-11 mph. The ramp from westbound Grand Central Parkway towards Stadium Road and the northbound Whitestone Expressway would deteriorate from LOS B to LOS F during the weekday and Saturday pre game peak hours and would experience a corresponding reduction in average travel spend from about 42 mph to 3 mph in the weekday pre game peak hour and from 44 mph to 1 mph in the Saturday pre game peak hour. The ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the weekday pre-game peak hour, and would deteriorate from LOS E to LOS F in the Saturday pre-game peak hour where it would also experience a drop in average travel speed from about 26 mph to 47 16 mph.~~

PROBABLE IMPACTS OF THE PROPOSED PROJECT

The proposed project would generate a significant number of trips during all analyzed peak hours on both directions of the Van Wyck Expressway and the Whitestone Expressway. The eastbound Grand Central Parkway mainline and the east side of the westbound Grand Central Parkway mainline split would also experience a higher volume during the peak hours. Overall, highway conditions would generally deteriorate or remain the same under the Phase 1A, Phase 1B and Phase

2 With Action conditions as compared to the No Action condition; however, in some instances, speeds and levels of service improved slightly between the No Action and With Action conditions. The two reasons for these improvements are: (1) the diversion of Mets fans to alternate ramps which are more convenient to the newly relocated Mets fan parking facilities (during game day peak hours), and (2) the saturation of one analyzed mainline or ramp, which causes a metering of vehicles arriving at (and consequential improvement of) downstream analysis locations.

The following sections provide a description of expected highway volume increments, resulting levels of service, and the identification of significant adverse highway impacts for each of the three buildout phases.

PHASE 1A (2018) WITH ACTION CONDITIONS

The Phase 1A With Action volumes on the eastbound mainline of the Grand Central Parkway north of Roosevelt Avenue would increase by approximately 450 to 1,000 vehicles during all seven peak hours, a roughly 14 to 29 percent increase compared to 2018 No Action volumes; the east side of the westbound Grand Central Parkway split would increase by 185 to 570 vph, a 7 to 23 percent increase. The Whitestone Expressway would experience volume increases of approximately 50 to 205 vph in the northbound and southbound directions, an approximate 1 to 4 percent increase per direction compared with the No Action volumes. The Van Wyck Expressway volumes would increase by about 50 to 100 vph in the northbound direction during non-game and post-game peak hours and an overall net decrease by 205 to 225 vph during game day peak hours (due to the game day circulation changes resulting from relocated CitiField parking facilities), and would range between a 5 percent decrease and a 5 percent increase compared to the No Action volume during peak hours. Volumes along the southbound Van Wyck Expressway would increase by 120 to 450 during all peak hours, which is an increase of about 4 to 12 percent over the No Action volumes.

NON-GAME DAY

Table 14-71 shows the Phase 1A With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the non-game-day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Mainlines

Under the Phase 1A With Action condition, the east side of the westbound Grand Central Parkway mainline split would deteriorate ~~from LOS B to LOS E during the weekday midday peak hour (density increase of approximately 25 pc/mi/ln), from LOS C to unacceptable LOS D during the weekday PM peak hour (density increase of 8 pc/mi/ln), and from LOS C to unacceptable LOS F D~~ (density increase of ~~80~~ 5 pc/mi/ln) during the Saturday midday peak hour and would be significantly impacted. The west side of the westbound Grand Central Parkway mainline split would deteriorate ~~from within LOS E to LOS F during the Saturday midday peak hour (density increase of 44~~ 3 pc/mi/ln) and would be significantly impacted. The southbound Van Wyck Expressway would deteriorate from LOS D to LOS E (density increase of 9 pc/mi/ln) during the weekday PM peak hour and would be significantly impacted. The northbound Whitestone Expressway would deteriorate within LOS F (density increase of 4 pc/mi/ln) during the weekday PM peak hour and would be significantly impacted. The southbound Whitestone Expressway would operate at LOS F (as in the No Action) during the weekday AM peak hour and would be significantly impacted (density increase of ~~24~~ 21 pc/mi/ln), and would deteriorate from LOS D to LOS E during the Saturday midday peak hour (density increase of ~~9~~ 5 pc/mi/ln). Average speeds along the significantly impacted segments would decrease by 1 to ~~33~~ 8 mph, the most significant of

which would occur on the ~~east side of the westbound Grand Central Parkway mainline split southbound Whitestone Expressway~~ during the ~~Saturday midday Weekday AM~~ peak hour.

Ramps

The ramp from the northbound Van Wyck Expressway to ~~westbound~~ eastbound Northern Boulevard would deteriorate from marginally unacceptable LOS D to unacceptable LOS E during

the non-game weekday AM peak hour and would be significantly impacted (density increase of 32 pc/l/mi). The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS C to unacceptable LOS D during the weekday PM peak hour and would be significantly impacted (density increase of 12 pc/mi/l/mi). The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard would deteriorate from an acceptable LOS C to unacceptable LOS F during the weekday midday, weekday PM, and Saturday midday peak hours where average travel speeds would drop from 30-35 mph to 4-9 mph, and would be significantly impacted (density increases of approximately 100-110 120 pc/l/mi). ~~Similarly, the ramp from the westbound Grand Central Parkway toward Stadium Road and the Northbound Whitestone Expressway would deteriorate from LOS A to LOS F during the weekday midday, weekday PM, and Saturday midday peak hours where average travel speeds would drop from 41-44 mph to less than 6 mph, and would be significantly impacted (density increases ranging from approximately 65-190 pc/l/mi).~~ Also, the ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the weekday AM peak hour and would deteriorate from LOS B to LOS F during the weekday midday and Saturday midday peak hours and would deteriorate from LOS C to LOS F during the ~~other two~~ weekday PM peak hours, and would be significantly impacted during all non-game peak hours (density increases of 40 ~~approximately 45~~ to 145 ~~175~~ pc/l/mi). Average speeds at this ramp would drop from 15-30 ~~43~~ mph to 3-14 ~~4-13~~ mph during non-game peak hours.

GAME DAY

Table 14-72 shows the Phase 1A With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the game day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Mainlines

Under the Phase 1A With Action condition, ~~the east side of the westbound Grand Central Parkway mainline split would continue to operate at LOS F during the Saturday pre-game peak hour (density increase of 61 pc/mi/l/mi) and would be significantly impacted. The southbound Whitestone Expressway would continue to operate at LOS F during the weekday pre-game peak hour and would deteriorate from LOS D to LOS F during the Saturday pre-game peak hour and would be significantly impacted (with a density increases of about 20 and 76 55 pc/mi/l/mi, respectively).~~ Average speeds along ~~the impacted segments~~ this segment would decrease by 4 ~~to 24 25~~ mph, ~~the most significant of which would occur on the southbound Whitestone Expressway mainline during the Saturday pre-game peak hour.~~

Ramps

The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from LOS C to unacceptable LOS E during the weekday pre-game peak hour and would be significantly impacted (density increase of 19.3 pc/ln/mi). The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS D to LOS E during the Saturday post-game peak hour and would be significantly impacted (density increase of 10.4 13.0 pc/ln/mi). The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard would continue to operate at LOS F during the weekday and Saturday pre-game peak hours and would deteriorate from an acceptable LOS D to unacceptable LOS F during the Saturday post-game peak hour and would be significantly impacted (density increases of approximately 22 pc/ln/mi during both pre-game peak hours and about 75 102 pc/ln/mi during

the Saturday post-game peak hour). The ramp from the westbound Grand Central Parkway toward Stadium Road and the ~~N~~orthbound Whitestone Expressway would deteriorate from LOS A/B to LOS F during the ~~weekday pre-game and~~ Saturday post-game peak hours ~~and would continue to operate at LOS F during the Saturday pre-game peak hour~~, and would be significantly impacted ~~during all game day peak hours~~ (density increases ~~from~~ of approximately ~~115-123~~ 88 pc/l/mi). Also, the ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the ~~weekday and~~ Saturday pre-game peak hours, and would be significantly impacted (density increases of ~~about 43 to 135.8~~ 97 pc/l/mi, respectively). Average speeds at the significantly impacted ramp locations would drop to 9 mph or less except for the ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway which would continue to operate at around 25 mph compared to the Phase 1A No Action condition.

Mitigation measures to improve overall highway network conditions are discussed in Chapter 21; ~~“Mitigation.”~~

PHASE 1B (2028) WITH ACTION CONDITIONS

The Phase 1B With Action volumes on the eastbound mainline of the Grand Central Parkway north of Roosevelt Avenue would increase by approximately 450 to 1,550 vehicles during all seven peak hours, a roughly 10 to 45 percent increase compared to 2028 No Action volumes; the east side of the westbound Grand Central Parkway split would increase by 340 to 750 vph, a 13 to 30 percent increase. The Whitestone Expressway would experience volume increases of approximately 110 to 365 vph in the northbound and southbound directions, an approximate 2 to 6 percent increase per direction compared with the No Action volumes. The Van Wyck Expressway volumes would increase by about 370 to 600 vph in the northbound direction during non-game and post-game peak hours and by 235 to 390 vph during game day peak hours, which are slightly lower due to the game day diversions of CitiField trips to the relocated parking lots. These increments represent a 5 to 15 percent increase compared to the No Action volume during all peak hours. Volumes along the southbound Van Wyck Expressway would increase by 385 to 965 during all peak hours, which is an increase of about 12 to 25 percent over the No Action volumes. The substantial increases on the Van Wyck Expressway in both directions would be due to traffic entering from and exiting to the new access ramps connecting the highway to the District.

NON-GAME DAY

Table 14-73 shows the Phase 1B With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the non-game-day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Table 14-73
Phase 1B (2028) With Action Highway Levels of Service Summary
Non-Game Day

Mainlines	Weekday AM			Weekday Midday			Weekday PM			Saturday Midday		
	Speed (mph)	Density (pc/mi/ln)	LOS	Speed (mph)	Density (pc/mi/ln)	LOS	Speed (mph)	Density (pc/mi/ln)	LOS	Speed (mph)	Density (pc/mi/ln)	LOS

Note: Highlight indicates a significant impact												

Mainlines

Because of the increase in volume on the highway network, most analyzed highway mainline locations would operate at LOS D, E or F during most of the non-game day peak hours, with the exception of the northbound Whitestone Expressway which would operate at LOS ~~B~~ C during the weekday AM, weekday midday, and Saturday midday peak hours, and the east side of the westbound Grand Central Parkway split which would operate at LOS C during the weekday

AM peak hour. Under the Phase 1B With Action condition, the east side of the westbound Grand Central Parkway mainline split would deteriorate from acceptable LOS B₂ and C₂ and D to LOS F during the weekday midday, weekday PM, and Saturday midday peak hours (density increases of approximately ~~127 to 156~~ 28 to 86 pc/mi/ln) compared to the Phase 1B No Action condition and would be significantly impacted. Average travel speeds along this segment would decrease from around 40 mph to 2 18 mph or less during these peak hours. The west side of the westbound Grand Central Parkway mainline split would deteriorate from LOS C₂, D and E to LOS D₂, E₂ and F during the weekday midday, weekday PM and Saturday midday peak hours and would be significantly impacted (density increases of about ~~9 to 17~~ 4 to 7 pc/mi/ln). Average travel speeds along this segment would drop approximately ~~5 to 10~~ 1 to 5 mph (to the ~~33 to 40~~ 40 to 45 mph range) during these peak hours. The northbound Van Wyck Expressway would deteriorate to LOS E or F during all non-game peak hours and would be significantly impacted. Density increases along this segment would range from approximately 5 to ~~23~~ 7 pc/mi/ln and average travel speeds would drop by 1 to ~~18~~ 2 mph, ~~the most significant of which would occur during the weekday midday peak hour.~~ The southbound Van Wyck Expressway mainline would deteriorate from LOS ~~D~~ C to LOS E in the weekday AM peak hour; LOS C to unacceptable LOS D in the weekday midday peak hour; and unacceptable LOS D to LOS E in the weekday PM peak hour, and would be significantly impacted (density increase of about ~~8~~ 5 to 9 pc/mi/ln). The southbound Whitestone Expressway would operate at LOS F during all non-game day peak hours and would be significantly impacted (density increases of ~~20 to 86~~ 8 to 85 pc/mi/ln). Average speeds along this segment would decrease by ~~12~~ 5 to 26 mph.

Ramps

~~The ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from marginally acceptable LOS D to unacceptable LOS D during the Saturday midday peak hour and would be significantly impacted (density increase of 11 pc/ln/mi).~~ The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from LOS B₂, C₂ and D to LOS E and F during weekday AM, midday, and PM, and Saturday midday peak hours, and would be significantly impacted (density increases of 3 to ~~94~~ 20 pc/ln/mi). Average travel speeds on this ramp would drop by ~~10 to 20~~ 8 mph or less during these peak hours. ~~The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS C to LOS F during the weekday PM peak hour and would be significantly impacted (density increase of 49 pc/ln/mi), and would experience an 8 mph drop in average travel speed (from 55 mph to 47 mph).~~ The ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway would deteriorate from acceptable LOS C₂ and D to unacceptable LOS D during the weekday PM and Saturday midday peak hours and would be significantly impacted (density increase of ~~6~~ 5 to 11 pc/ln/mi). Three ramps, from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard, from the westbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway, and from the southbound Whitestone Expressway to westbound Northern Boulevard, would all deteriorate from mostly LOS A, B and C to LOS F during all non-game peak hours with the exception of the ramp from the westbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway during the weekday AM peak hour, and would be significantly impacted (density increases of ~~97 to 239~~ 76 to 221 pc/ln/mi). Average travel speeds along these ramps would drop by ~~6~~ 2 to 44 mph, and all impacted ramps would experience average speeds of 4 7 mph or less.

GAME DAY

Table 14-74 shows the Phase 1B With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the game day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Mainlines

Under Phase 1B With Action conditions on a day with a Mets game, most analyzed highway mainline locations would operate at LOS D, E or F during pre-game and post-game peak hours. The east side of the westbound Grand Central Parkway mainline split ~~would continue to operate at LOS F during the Saturday pre-game peak hour and~~ would deteriorate from LOS D to LOS F ~~and during the Saturday post-game pre-game peak hour and~~ would be significantly impacted (with ~~density increases of 59 and 17~~ a density increase of 16 pc/mi/ln, ~~respectively~~). Average speeds along the impacted segments would decrease by ~~44 to 44~~ approximately 12 mph. The west side of the westbound Grand Central Parkway mainline split would operate at LOS E during all game day peak hours and would be significantly impacted during the Saturday post-game peak hour (density increase of approximately 3 2 pc/mi/ln). The northbound Van Wyck Expressway would continue to operate at LOS E during all game day peak hours (density increases of 2 to 4 pc/mi/ln) and would be significantly impacted. The southbound Van Wyck Expressway would continue to operate at LOS E during the weekday pre-game peak hour and would be significantly impacted (density increase of approximately 6 pc/mi/ln). ~~The northbound Whitestone Expressway would continue to operate at LOS E during the weekday pre-game peak hour (density increase of 2 pc/mi/ln) and would be significantly impacted.~~ The southbound Whitestone Expressway would deteriorate from LOS D to LOS ~~F~~ E during the Saturday pre-game peak hour and would be significantly impacted (density increases of ~~34~~ 11 pc/mi/ln). The average travel speed along this segment would decrease by about ~~49~~ 9 mph (from 34 mph to ~~45~~ 25 mph).

Ramps

The ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from ~~LOS C acceptable~~ LOS D to unacceptable LOS D during the Saturday pre-game peak hour and would be significantly impacted (density increase of 5 pc/ln/mi). The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS ~~B C~~ to LOS ~~F~~ E during the ~~Saturday weekday~~ Saturday pre-game peak hour and would be significantly impacted (density increase of ~~49~~ about 22 pc/ln/mi). The average travel speed at this ramp would decrease by ~~33~~ 15 mph (~~to 2 mph~~) during the impacted peak hour. The ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway would deteriorate from marginally acceptable LOS D to unacceptable LOS ~~D~~ E during the Saturday pre-game peak hour and would be significantly impacted (density increase of 7 about 16 pc/ln/mi).

Note: Highlight indicates a significant impact									

Three ramps providing direct access to the District would be significantly impacted during all game day peak hours; however, they would generally be impacted to a lesser degree as compared to Phase 1A. This is because the Mets game-generated traffic that would use these ramps to access interim parking within the district would be diverted to the replacement parking facilities south of Roosevelt Avenue under Phases 1B and 2, and thus would no longer use these ramps. The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard would continue to operate at LOS F during the weekday and Saturday pregame peak hour, and would deteriorate from marginally acceptable LOS D to unacceptable LOS F during the Saturday post-game peak hour and would be significantly impacted (density increases of approximately 7 to 9 pc/ln/mi during both pre-game peak hours and about 86 of approximately 81 pc/ln/mi during the Saturday post-game peak hour). The average travel speed at this ramp would decrease by 29 26 mph

during the Saturday post-game peak hour and would operate with average speeds of ~~4 to 7~~ 6 to 19 mph during game day peak hours. The ramp from the westbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway would deteriorate from LOS A and B to LOS F during the ~~weekday~~ Saturday pre-game and Saturday post-game peak hours ~~and would continue to operate at LOS F during the Saturday pre-game peak hour~~, and would be significantly impacted ~~during all game day peak hours~~ (density increases ranging from approximately ~~38-180~~ 46 to 162 pc/ln/mi). Average travel speeds during these two peak hours at this location would range from ~~1 to 16~~ 2 to 14 mph (decreasing by ~~26 mph during weekday pre-game and 41~~ 39 mph during Saturday post-game conditions). Also, the ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the Saturday pre-game peak hour ~~and would deteriorate from LOS B to unacceptable LOS D during the Saturday post-game peak hour~~, and would be significantly impacted during the Saturday pre-game ~~and post-game~~ peak hours (density increases of ~~7 to~~ 55 pc/ln/mi).

Mitigation measures to improve overall highway network conditions are discussed in Chapter 21, “~~Mitigation~~.”

PHASE 2 (2032) WITH ACTION CONDITIONS

The Phase 2 With Action condition encompasses the entire proposed development program and Lot B development trips. As a result, volumes on the eastbound mainline of the Grand Central Parkway north of Roosevelt Avenue would increase by approximately 950 to 2,100 vehicles during all seven peak hours, a roughly 17 to 52 percent increase compared to 2032 No Action conditions; the east side of the westbound Grand Central Parkway split would increase by 500 to 950 vph, a 19 to 40 percent increase. The Whitestone Expressway would experience volume increases of approximately 175 to 600 vph in the northbound and southbound directions, an approximate 3 to 11 percent increase per direction compared with the No Action volumes. The Van Wyck Expressway volumes would increase by about 700 to 1,100 vph in the northbound direction during non-game and post-game peak hours and by 500 to 750 vph during game day peak hours, which are slightly lower due to the game day diversions of CitiField trips to the relocated parking lots. These increments represent an 11 to 27 percent increase compared to the No Action volume during all peak hours. Volumes along the southbound Van Wyck Expressway would increase by 650 to 1,600 vph during all peak hours, which is an increase of about 21 to 41 percent over the No Action volumes. The substantial increases on the Van Wyck Expressway in both directions would be due to traffic entering from and exiting to the new access ramps connecting the highway to the District.

NON-GAME DAY

Table 14-75 shows the Phase 2 With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the non-game-day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Table 14-75

Mainlines

Because of the increase in volume on the highway network under the Phase 2 With Action, most analyzed highway mainline locations would operate at LOS D, E or F during most of the non-game day peak hours, with the exception of the northbound Whitestone Expressway which would operate at LOS B and C during the weekday AM, weekday midday, and Saturday midday peak hours, and the eastbound Grand Central Parkway split which would operate at LOS C

during the weekday and Saturday midday peak hours, and the east side of the westbound Grand Central Parkway mainline split which would operate at LOS C during the weekday AM peak hour, and the southbound Van Wyck Expressway mainline which would operate at LOS C during the weekday midday peak hour.

The east side of the westbound Grand Central Parkway mainline split would deteriorate from LOS B, C, or D to LOS F during ~~all the weekday midday, PM, and Saturday midday non-game peak hours~~ (density increases of approximately ~~49 to 172~~ 112 to 130 pc/mi/lane) compared to the Phase 2 No Action condition and would be significantly impacted. Average travel speeds along this segment would decrease from the ~~40-50~~ 35 to 45 mph range to ~~6-4~~ mph or less during the weekday midday, PM, and Saturday midday peak hours. The west side of the westbound Grand Central Parkway mainline split would deteriorate from LOS D and E to LOS E and F during ~~the weekday midday, weekday PM and Saturday midday peak hour~~ all non-game peak hours and would be significantly impacted (density increases of about ~~10 to 20~~ 2 to 17 pc/mi/lane). Average travel speeds along this segment would drop approximately ~~9 to 12~~ 1 to 16 mph (to the ~~30-35~~ 25 to 45 mph range) during these peak hours. The northbound Van Wyck Expressway would deteriorate to LOS F during all non-game peak hours and would be significantly impacted. Density increases along this segment would range from approximately ~~28 to 80~~ 9 to 44 pc/mi/lane and average travel speeds would drop by ~~11 to 30~~ 1 to 25 mph and would operate with speeds of ~~10 to 22~~ 14 to 33 mph, the most significant of which would occur during the weekday midday peak hour. ~~The southbound Van Wyck Expressway mainline would deteriorate from marginally acceptable LOS D to unacceptable LOS D in the weekday AM peak hour and would be significantly impacted (density increase of about 5 pc/mi/lane).~~ The southbound Whitestone Expressway would operate at LOS F during all non-game day peak hours and would be significantly impacted (density increases of ~~10 to 116~~ 30 to 118 pc/mi/lane). Average speeds along this segment would decrease by ~~6 to 29~~ 14 to 30 mph.

Ramps

The ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from ~~LOS B, C or marginally acceptable LOS D during the non-game weekday midday, weekday PM and Saturday midday peak hours~~ LOS C to unacceptable LOS D during the Saturday midday peak hour and would be significantly impacted (density increases of ~~25 to 35~~ about 7 pc/lane/mile), ~~with average travel speeds decreasing (by about 15 mph) to the 7-10 mph range.~~ The ramp from the northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from LOS ~~B, C~~ and D to LOS F during ~~all the weekday AM, midday, and Saturday midday peak hours~~ and to LOS E during the weekday PM peak hour, and would be significantly impacted (density increases of ~~23 to 73~~ 20 to 101 pc/lane/mile). Average travel speeds on this ramp would drop by about ~~10-8~~ to 20 mph during these peak hours, and would experience travel speeds of about ~~3 to 12~~ 15 mph. The ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway would deteriorate from marginally acceptable LOS D to LOS E during the Saturday midday peak hour and would be significantly impacted (density increase of ~~44~~ 6 pc/lane/mile). The ramp from the southbound Whitestone Expressway to the eastbound Grand Central Parkway would deteriorate from LOS B to LOS F during the weekday midday peak hour and would be significantly impacted (density increase of ~~37~~ 46 pc/lane/mile) with the average travel speed also decreasing to less than 1 mph.

Three ramps leading into the District—the ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard, the ramp from the westbound Grand Central Parkway toward Stadium Road and the ~~N~~ northbound Whitestone Expressway, and the ramp from the southbound Whitestone

Expressway to westbound Northern Boulevard would deteriorate from LOS A, B, and C, or D to LOS F or would continue to operate at LOS F during all non-game peak hours and would be significantly impacted (density increases of 97 to 239 101 to 226 pc/l/mi) ~~except at the ramp from the southbound Whitestone Expressway to Northern Boulevard during the weekday AM peak hour (which would continue to operate at LOS F but would not be impacted).~~ Average travel speeds along these ramps would drop by 6 to 44 2 to 43 mph, and all ramps would experience average speeds of 4 5 mph or less.

GAME DAY

Table 14-76 shows the Phase 2 With Action levels of service, speeds and densities for the highway sections and ramps analyzed during the game day peak hours. A discussion of these conditions and identification of significant impacts is provided below.

Mainlines

Under the Phase 2 With Action condition on a day with a Mets game, most analyzed highway mainline locations would operate at LOS D, E or F during pre-game and post-game peak hours. ~~The eastbound Grand Central Parkway mainline would deteriorate from LOS D to LOS E during the weekday pre-game peak hour and would be significantly impacted (density increase of about 2 pc/mi/l/mi).~~ The east side of the westbound Grand Central Parkway mainline split would operate at ~~LOS E or F unacceptable LOS D or LOS F during all game day the weekday pre-game and Saturday post-game~~ peak hours (density increases of about 45 5 pc/mi/l/mi during the weekday ~~and Saturday~~ pre-game peak hours and of 450 70 pc/mi/l/mi during the Saturday post-game peak hour) and would be significantly impacted. ~~Average travel speeds along this segment would decrease to less than 1 mph during Saturday pre-game and post-game peak hours.~~ The west side of the westbound Grand Central Parkway mainline split would deteriorate from LOS D to LOS E during the weekday pre-game peak hour and from LOS E to LOS F during the Saturday post-game peak hour and would be significantly impacted (density increases of 3 2 to 46 10 pc/mi/l/mi).

The northbound Van Wyck Expressway would continue to operate at LOS E or F during all game day peak hours and would be significantly impacted during ~~the Saturday pre-game and post-game~~ all game day peak hours (density increases of 9 to 52 5 to 8 pc/mi/l/mi). ~~The northbound Whitestone Expressway would continue to operate at LOS E during the weekday pre-game peak hour (density increase of 3 pc/mi/l/mi) and would be significantly impacted.~~ The southbound Whitestone Expressway would deteriorate to LOS F during all game day peak hours and would be significantly impacted (density increases of 49 18 to 23 34 pc/mi/l/mi). The average travel speed along this segment would decrease by about 0.5 4 mph during the weekday pre-game peak hour and 13-16 13-20 mph during the Saturday pre-game and post-game peak hours.

Ramps

The ramp from the northbound Van Wyck Expressway to eastbound Northern Boulevard would deteriorate from LOS C and marginally acceptable LOS D to unacceptable LOS D, or E or F during the three game day peak hours and would be significantly impacted (density increases of 7 to 30 6 to 8 pc/in/mi). The ramp from northbound Van Wyck Expressway to westbound Northern Boulevard would deteriorate from LOS B to LOS E during the Saturday post game peak hour and would be significantly impacted (density increase of 33 pc/in/mi), and would also decrease to an average travel speed of 11 mph. The ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway would deteriorate from LOS B to LOS F during the Saturday pre game peak hour and would be significantly impacted (density increase of 56 pc/in/mi). The ramp from westbound Northern Boulevard to the southbound Van Wyck Expressway would deteriorate from marginally acceptable LOS D to unacceptable LOS F during

the Saturday pre-game peak hour and would be significantly impacted (density increase of ~~42~~ 49 pc/l/mi). The average travel speed along this ramp would also decrease to 11 mph during this peak hour. ~~The ramp from eastbound Astoria Boulevard and eastbound Northern Boulevard to the northbound Whitestone Expressway would deteriorate from LOS A to LOS F during the Saturday pre-game peak hour (density increase of 37 pc/l/mi and would be significantly impacted). This ramp would experience a reduction in travel speed from 40 mph to 3 mph.~~ The ramp from eastbound Astoria Boulevard and the Grand Central Parkway to the northbound Whitestone Expressway and eastbound Northern Boulevard ~~would continue to operate at LOS F during the Saturday pre-game peak hour and~~ would deteriorate from marginally acceptable LOS D to unacceptable LOS F during the Saturday post-game peak hour and would be significantly impacted (density increases of ~~10~~ 104 pc/l/mi during the Saturday pre-game peak hour and 118 pc/l/mi during the Saturday post-game peak hour). The average travel speed at this ramp would decrease to ~~4 to 6~~ 5 mph during ~~all game-day peak hours~~ the Saturday post-game peak hour. The ramp from the westbound Grand Central Parkway toward Stadium Road and the northbound Whitestone Expressway would deteriorate from LOS A to LOS F during the Saturday post-game peak hour and would ~~continue to operate at~~ deteriorate from LOS C to LOS F during the ~~weekday and~~ Saturday pre-game peak hours, and would be significantly impacted during ~~all game-day these~~ these peak hours (density increases ranging approximately ~~37 to 218~~ 108 to 190 pc/l/mi). Average travel speeds at this location would be ~~7~~ 5 mph or less during ~~all the Saturday pre-game and post-game~~ the Saturday pre-game and post-game time periods. Also, the ramp from the southbound Whitestone Expressway to westbound Northern Boulevard would continue to operate at LOS F during the weekday and Saturday pre-game peak hours and would deteriorate from LOS B to LOS F during the Saturday post-game peak hour, and would be significantly impacted (density increases of ~~44 to 117~~ 42 to 118 pc/l/mi). The average travel speed at this location would decrease to ~~8~~ 7 mph or less during game day peak hours.

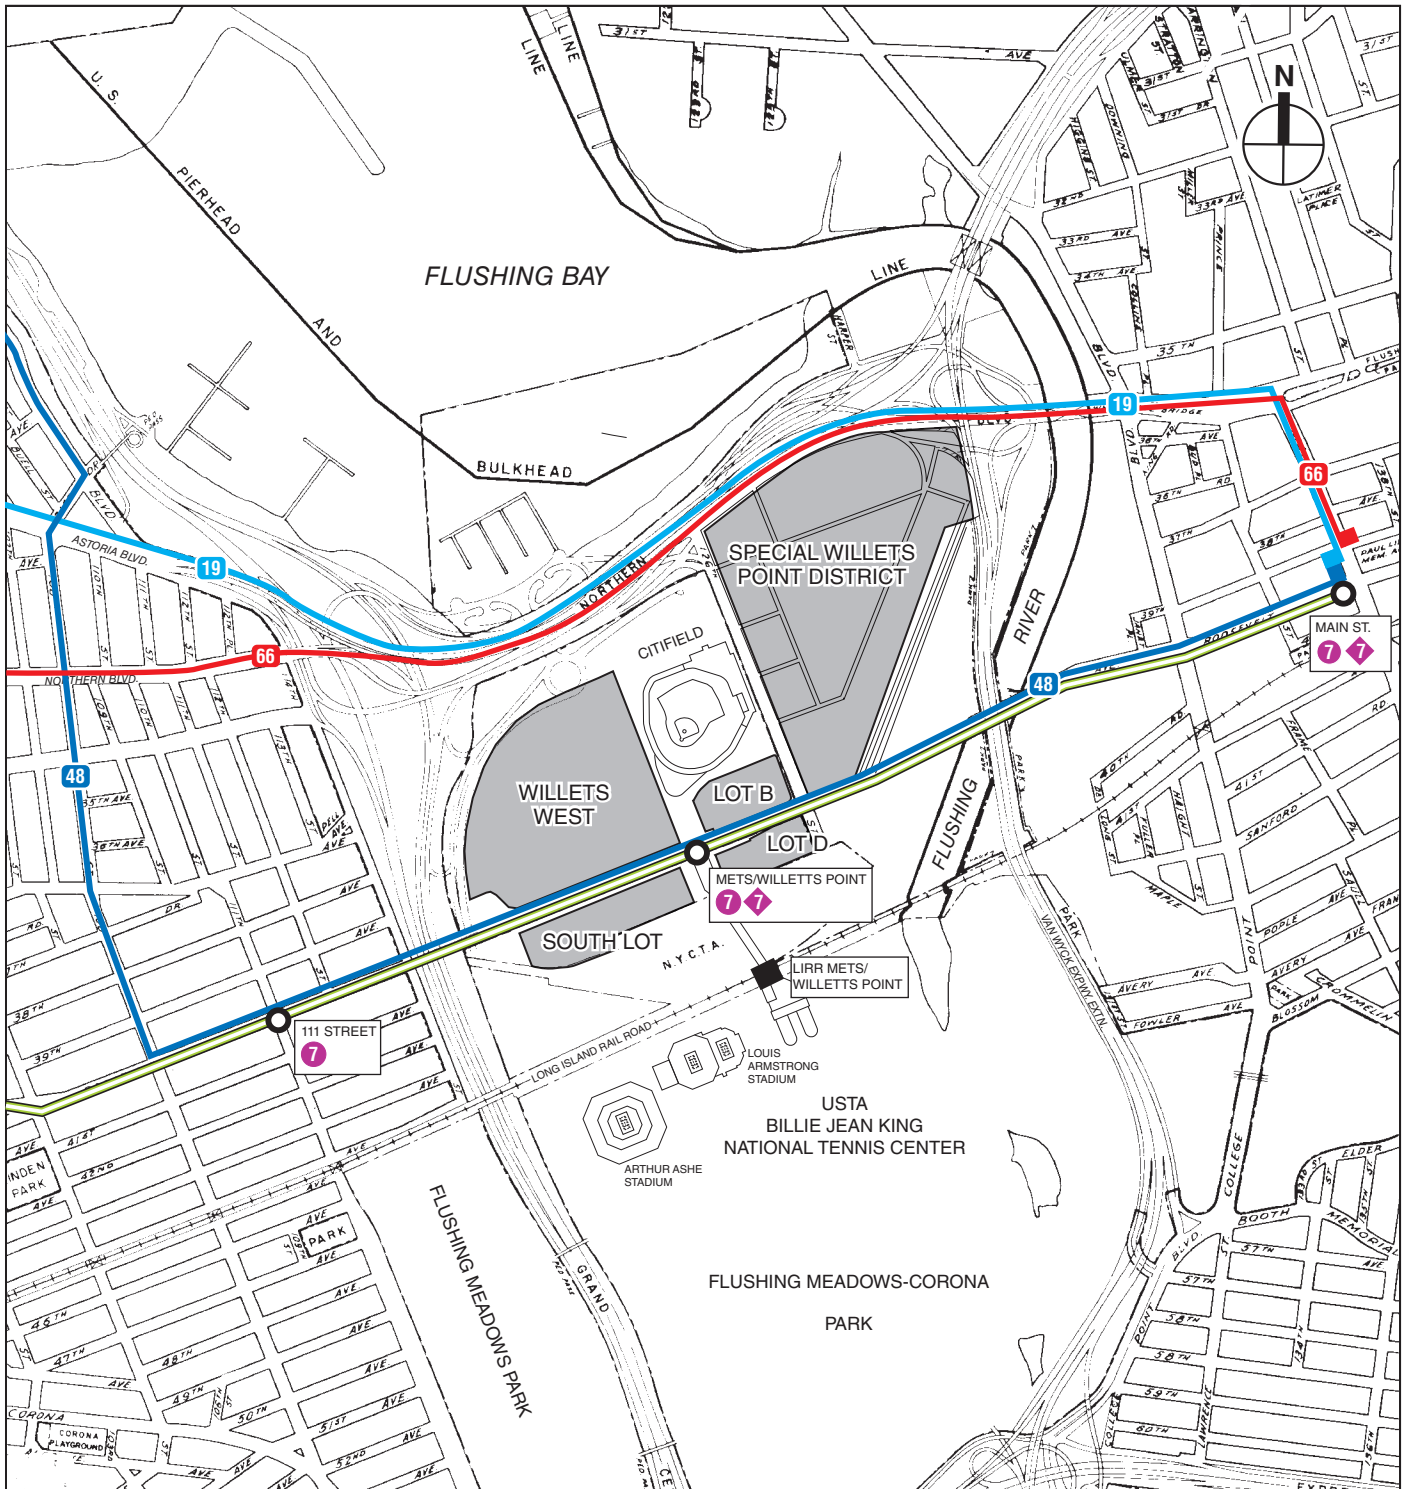

Mitigation measures to improve overall highway network conditions are discussed in Chapter 21, “Mitigation.”

H. SCOPE OF ANALYSIS (TRANSIT AND PEDESTRIANS)

As described in the “Traffic and Parking” section, a travel demand projection was developed to identify the transportation elements likely to be affected by the proposed project. Because the number of peak hour transit and pedestrian trips generated by the proposed project would exceed the 200 trip per hour threshold specified in the 2012 *City Environmental Quality Review (CEQR) Technical Manual*, quantified transit and pedestrian analyses are required.

TRANSIT AND PEDESTRIAN STUDY AREAS

Mass transit options serving the project site include the Metropolitan Transportation Authority (MTA) New York City Transit (NYCT) No. 7 subway line, which operates above Roosevelt Avenue with a stop at the Mets-Willets Point subway station; the MTA Bus Company Q19 and Q66, and NYCT Q48 bus routes, which travel along the northern and southern boundaries of CitiField and the District; and the MTA Long Island Rail Road (LIRR) at the Mets-Willets Point LIRR station (game-day service only), which is accessible just south of the project site (see **Figure 14-4**). The transit analyses include a quantified assessment of control areas and circulation elements at the No. 7 Mets-Willets Point subway station, a ridership and peak period train loading analysis for the No. 7 subway line, and a line-haul analysis for the Q19, Q48, and Q66 bus routes, which includes assessments of conditions at peak load points and at nearby bus stops. In addition, because NYCT expects that there would be notable transfer activities between

- Project Site
- Local Bus Route
- Local Bus Route Number
- Subway Route and Station

0 1000 2000 FEET
SCALE

the No. 7 line and the N/Q lines at the Queensboro Plaza subway station (across the platform transfers), a detailed examination of line-haul conditions on the N/Q lines ~~will be~~ was prepared, in coordination with NYCT, ~~as part of this for the~~ Final SEIS. During the preparation of the 2008 FGEIS, the City had consulted with the MTA on extending regular LIRR service to the Mets-Willets Point station when the actual demand shows ~~that such~~ service improvement is warranted; ~~h-~~ However, because LIRR service is currently available only on game days at CitiField and at the United States Tennis Association (USTA) National Tennis Center (NTC) during the US Open, no quantified impact analysis was conducted for this transportation mode. The evaluation of pedestrian flow includes an analysis of the sidewalks, corner reservoirs, and crosswalks adjacent to CitiField and the District, along 114th Street, 126th Street, Northern Boulevard, and Roosevelt Avenue (see **Figure 14-5**). In addition, related pedestrian analyses ~~were~~ will be prepared for the three intersections (126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place) where additional traffic analyses ~~were~~ will also be conducted and ~~are~~ are presented in ~~this e~~ this Final SEIS.

SUBWAY SERVICE

No. 7 line

The No. 7 subway line operates primarily along Roosevelt Avenue between Flushing, Queens, and midtown Manhattan. Local service is available 24 hours a day, and express service is available during the weekday AM peak period for travel to Manhattan and during the weekday PM peak period for travel to Flushing. Unscheduled express service is also supplemented during game days at CitiField and during the US Open. From 6:21 AM to 9:55 AM, the No. 7 train operates express service every 2 to 5 minutes and local service every 4 to 6 minutes to Manhattan. Flushing-bound, the No. 7 operates local every 3 to 6 minutes from 6:30 AM to 2:50 PM. The Flushing-bound express service begins at 2:55 PM and ends at 9:38 PM. Between 4:03 PM and 8:45 PM, the Flushing-bound No. 7 train operates express service every 2 to 5 minutes and local service every 5 to 8 minutes. When games occur on weekday evenings, there is express service to Manhattan for an hour after the end of the game. On Saturdays, there is local service every 4 to 6 minutes in both directions. On Sundays, the No. 7 train operates every 8 minutes during the morning and every 6 minutes during the afternoon in both directions.

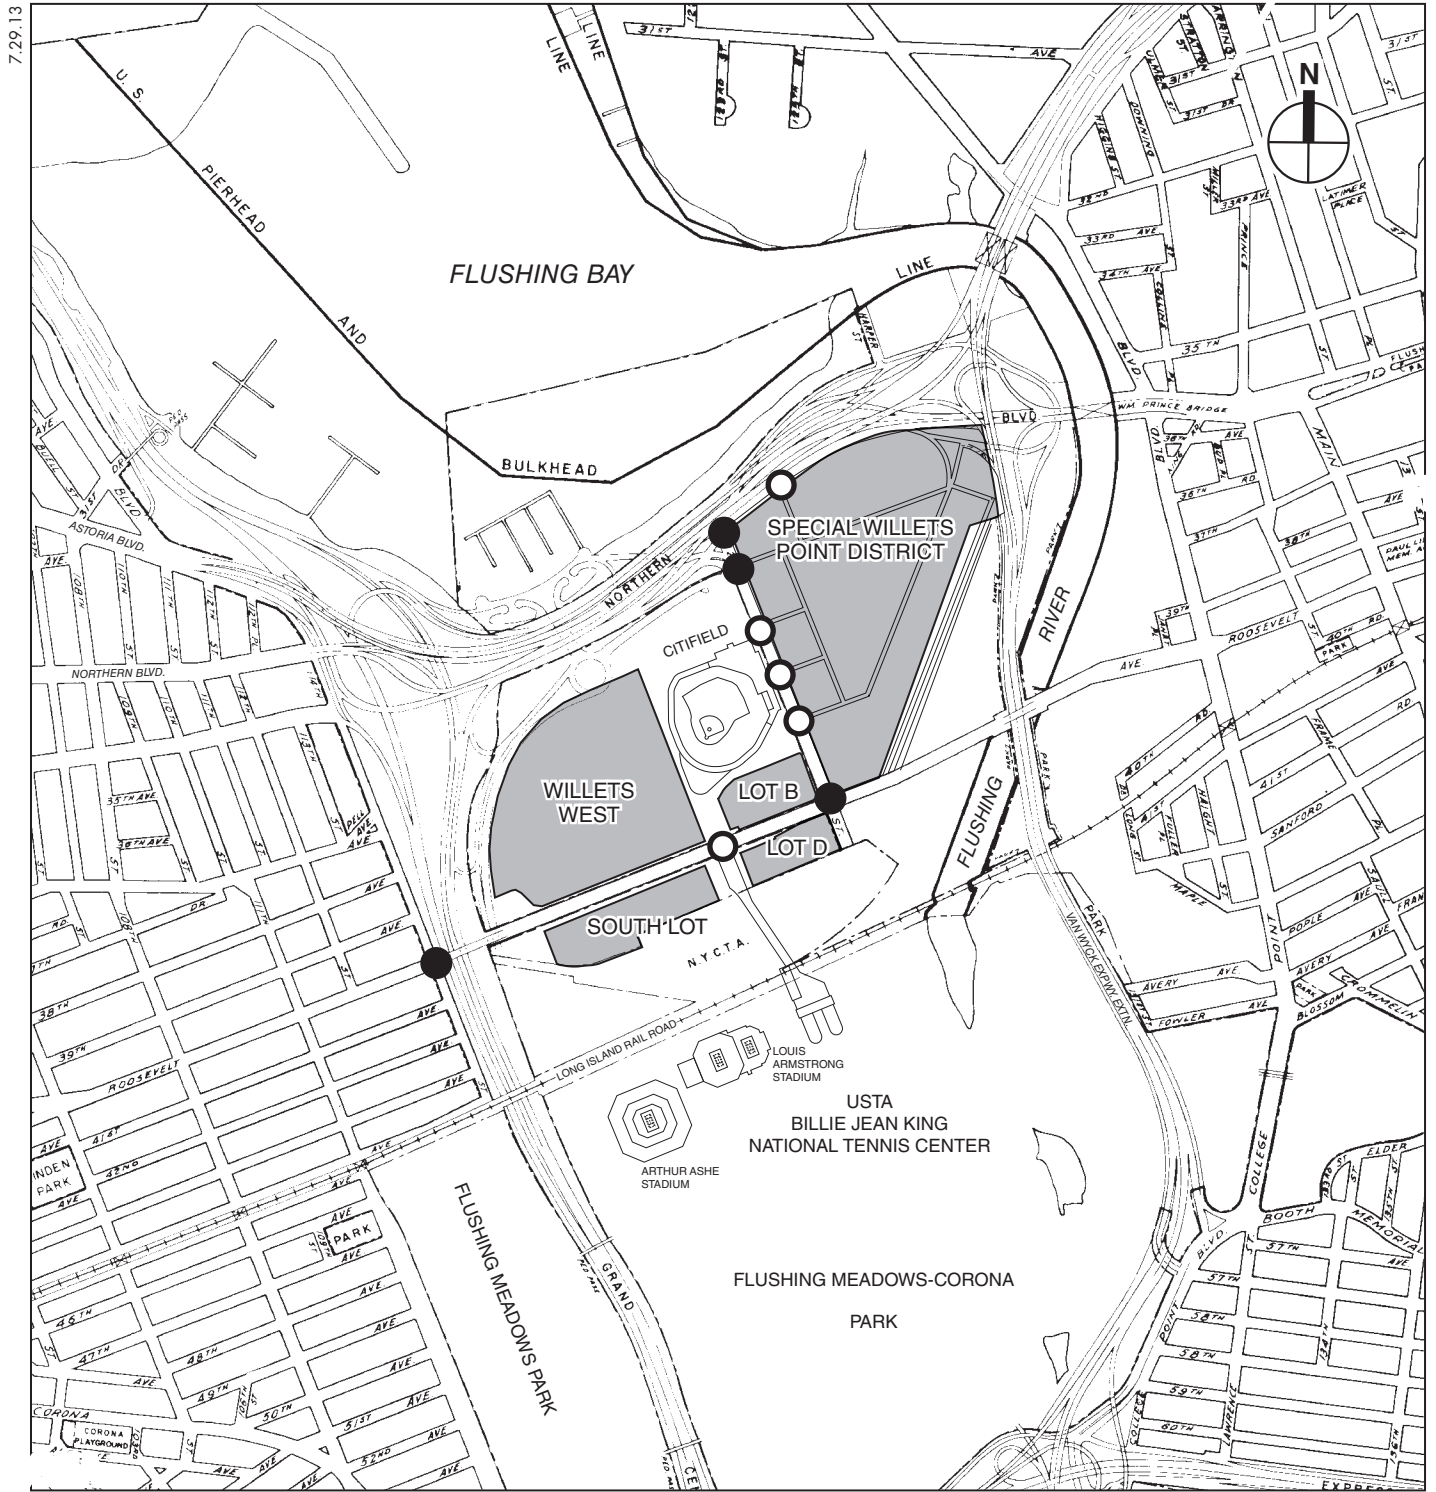

N/Q lines

The N subway line operates between Ditmars Boulevard, Queens, and Stillwell Avenue, Brooklyn at all times. It operates local in Queens and Manhattan and either express or local in Brooklyn depending on the time of day. During AM and PM commuter peak hours it operates with 6 to 8 minute headways.

The Q subway line operates between 57th Street/Seventh Avenue, Manhattan, and Stillwell Avenue, Brooklyn at all times, except weekdays from about approximately 6 AM to 11 PM when the route extends to operate between Astoria, Queens, and Stilwell Avenue, Brooklyn. The Q line operates express via Broadway to Canal Street. During AM and PM commuter peak hours it operates with 10 to 12 minute headways.

BUS SERVICE

There are three study area bus routes, Q48 operated by NYCT, and Q19 and Q66 operated by the MTA Bus Company. The Q48 operates between Flushing and LaGuardia Airport and makes stops in both eastbound and westbound directions within the study area along Roosevelt Avenue. The Q19 operates between Flushing and Astoria and the Q66 operates between Flushing and Long Island City and stops within the study area along Northern Boulevard. While the Q66

- Project Site
- Study Area Intersections Analyzed
- Intersections Added for Analysis under the future with the Proposed Project

0 1000 2000 FEET
SCALE

Willets Point Development

makes stops in both eastbound and westbound directions, the Q19 makes stops in the eastbound direction only within the study area. All of these routes use standard buses with a guideline capacity of 54 passengers per bus. **Table 14-77** provides a summary of the weekday and weekend service headways of these bus routes.

Table 14-77
Local Bus Routes Serving the Study Area

Bus Route	Start Point	End Point	Routing	Frequency of Bus Service (Headway in Minutes)				
				AM	Midday	PM	Pre-game Weekend	Post-game Weekend
Q19 (EB/WB)	Flushing	Astoria	via Northern Boulevard/ Astoria Boulevard	(20/20)	(20/20)	(20/20)	(30/30)	(30/30)

Q66 (EB/WB)	Flushing	Long Island City	via Northern Boulevard	(12/6)	(12/10)	(15/7-8)	(12/12)	(10/10)
Q66 (EB/WB)	Flushing	Woodside	via Northern Boulevard	(4-6/6)	(12/10)	(6/7-8)	(12/12)	(10/10)
Source: New York City Transit Bus Schedule(2011/2012)								

LIRR SERVICE

The Port Washington Branch of the LIRR operates regular weekday local and express service, and weekend local only service between Port Washington and Penn Station. On game days at CitiField and during the US Open, it makes stops at the Mets-Willets Point LIRR station to accommodate event patrons.

PEDESTRIAN ELEMENTS

Numerous sidewalks, corner reservoirs, and crosswalks surrounding the project site were identified for analysis. These pedestrian elements, representing locations where most of the project-generated trips would be anticipated, are situated primarily along 126th Street between Roosevelt Avenue and Northern Boulevard and along Roosevelt Avenue between 114th and 126th Streets. Where appropriate, new pedestrian elements contemplated as part of the proposed project were incorporated into the analysis of probable impacts of the proposed project.

OPERATIONAL ANALYSIS METHODOLOGY

SUBWAY STATION ELEMENTS

The methodology for assessing station circulation (stairs, escalators, and passageways) and fare control (regular turnstiles, high entry/exit turnstiles, and high exit turnstiles) elements compares the user volume with the analyzed element's design capacity, resulting in a volume-to-capacity (v/c) ratio.

For stairs, the design capacity considers the effective width of a tread, which accounts for railings or other obstructions, the friction or counter-flow between upward and downward pedestrians (up to 10 percent capacity reduction is applied to account for counter-flow friction), surging of exiting pedestrians (up to 25 percent capacity reduction is applied to account for detaining surges near platforms), and the average area required for circulation. For passageways, similar considerations are made. For escalators and turnstiles, capacities are measured by the number and width of an element and the NYCT optimum capacity per element,

also account for the potential for surging of exiting pedestrians. In the analysis for each of these elements, volumes and capacities are presented for 15-minute intervals.

The estimated v/c ratio is compared with NYCT criteria to determine a level of service (LOS) for the operation of an element, as summarized in **Table 14-78**.

Table 14-78
Level of Service Criteria for Subway Station Elements

LOS	V/C Ratio
A	0.00 to 0.45
B	0.45 to 0.70
C	0.70 to 1.00
D	1.00 to 1.33
E	1.33 to 1.67
F	Above 1.67
Source: New York City Mayor's Office of Environmental Coordination, <i>CEQR Technical Manual</i> (January 2012 edition).	

At LOS A (“free flow”) and B (“fluid flow”), there is sufficient area to allow pedestrians to freely select their walking speed and bypass slower pedestrians. When cross and reverse flow movement exists, only minor conflicts may occur. At LOS C (“fluid, somewhat restricted”), movement is fluid although somewhat restricted. While there is sufficient room for standing without personal contact, circulation through queuing areas may require adjustments to walking speed. At LOS D (“crowded, walking speed restricted”), walking speed is restricted and reduced. Reverse and cross flow movement is severely restricted because of congestion and the difficult passage of slower moving pedestrians. At LOS E (“congested, some shuffling and queuing”) and F (“severely congested, queued”), walking speed is restricted. There is also insufficient area to bypass others, and opposing movement is difficult. Often, forward progress is achievable only through shuffling, with queues forming.

Significant Impact Criteria

The determination of significant impacts for station elements varies based on their type and use. For stairs and passageways, significant impacts are defined in term of width increment threshold (WIT) based on the minimum amount of additional capacity that would be required either to mitigate the location to its service conditions (LOS) under the No Action levels, or to bring it to a v/c ratio of 1.00 (LOS C/D), whichever is greater. Significant impacts are typically considered to occur once the WITs in **Table 14-79** are reached or exceeded.

Table 14-79
Significant Impact Guidance for Stairs and Passageways

With Action V/C Ratio	WIT for Significant Impact (inches)	
	Stairway	Passageway
1.00 to 1.09	8.0	13.0
1.10 to 1.19	7.0	11.5
1.20 to 1.29	6.0	10.0
1.30 to 1.39	5.0	8.5
1.40 to 1.49	4.0	6.0
1.50 to 1.59	3.0	4.5
1.60 and up	2.0	3.0
Notes: WIT = Width Increment Threshold		
Sources: New York City Mayor's Office of Environmental Coordination, <i>CEQR Technical Manual</i> (January 2012 edition).		

For escalators and control area elements, impacts are significant if the proposed action causes a v/c ratio to increase from below 1.00 to 1.00 or greater. Where a facility is already at or above its capacity (a v/c of 1.00 or greater) in the No Action condition, a 0.01 increase in v/c ratio is also significant.

SUBWAY AND BUS LINE HAUL CAPACITIES

As per the *CEQR Technical Manual*, line-haul capacities are evaluated when a proposed action is anticipated to generate a perceptible number of passengers on particular subway and bus routes. For subways, if a subway line is expected to incur 200 or more passengers in one direction of travel during the commuter peak hours, a detailed review of ridership level at its maximum load point and/or other project-specific load points would be required to determine if the route's guideline (or practical) capacity would be exceeded. NYCT operates six different types of subway cars with different seating and guideline capacities. The peak period guideline capacity of a subway car, which ranges from 110 to 175 passengers, is compared with ridership levels to determine the acceptability of conditions.

Bus line-haul capacities are evaluated when a proposed action is anticipated to generate 50 or more bus passengers to a single bus line in one direction. The assessment of bus line-haul conditions involves analyzing bus routes at their peak load points and, if necessary, also their bus stops closest to the project site to identify the potential for the analyzed routes to exceed their guideline (or practical) capacities. NYCT and the MTA Bus Company operate three types of buses: standard and articulated buses, and over-the-road coaches. During peak hours, standard buses operate with up to 54 passengers per bus, articulated buses operate with up to 85 passengers per bus, and over-the-road coaches operate with up to 55 passengers per bus.

Significant Impact Criteria

For subways, projected increases from the No Action condition within guideline capacity to a With Action condition that exceeds guideline capacity may be a significant impact if the proposed project is generating five more transit riders per car. Since there are constraints on what service improvements are available to NYCT, significant line-haul capacity impacts on subway routes are generally disclosed but would usually remain unmitigated. For buses, an increase in bus load levels greater than the maximum capacity at any load point is defined as a potential significant adverse impact. While subject to operational and fiscal constraints, bus impacts can typically be mitigated by increasing service frequency. Therefore, mitigation of bus line-haul capacity impacts, where appropriate, would be recommended for NYCT's approval.

PEDESTRIAN OPERATIONS

The adequacy of the study area's sidewalks, crosswalks, and corner reservoir capacities in relation to the demand imposed on them is evaluated based on the methodologies presented in the 2010 HCM, pursuant to procedures detailed in the *CEQR Technical Manual*.

Sidewalks are analyzed in terms of pedestrian flow. The calculation of the average pedestrians per minute per foot (PMF) of effective walkway width is the basis for a sidewalk level of service (LOS) analysis. The determination of walkway LOS is also dependent on whether the pedestrian flow being analyzed is best described as "non-platoon" or "platoon." Non-platoon flow occurs when pedestrian volume within the peak 15-minute period is relatively uniform, whereas, platoon flow occurs when pedestrian volumes vary significantly with the peak 15-minute period. Such variation typically occurs near bus stops, subway stations, and/or where adjacent crosswalks account for much of the walkway's pedestrian volume. In addition to the pedestrian

flow, effective sidewalk width (i.e., part of the sidewalk that could be effectively used by pedestrians free of any obstructions) is another important parameter used in the analysis. In calculating the effective sidewalk width, the “shy distances” (i.e., the space left between pedestrians and building façades/curbs) are also taken into account.

Crosswalks and street corners are not easily measured in terms of free pedestrian flow, as they are influenced by the effects of traffic signals. Street corners must be able to provide sufficient space for a mix of standing pedestrians (queued to cross a street) and circulating pedestrians (crossing the street or moving around the corner). The HCM methodologies apply a measure of time and space availability based on the area of the corner, the timing of the intersection signal, and the estimated space used by circulating pedestrians.

The total “time-space” available for these activities, expressed in square feet-second, is calculated by multiplying the net area of the corner (in square feet) by the signal’s cycle length. ~~The analysis then determines the total circulation time for all pedestrian movements at the corner per signal cycle (expressed as pedestrians per second).~~ The total pedestrian occupancy time (pedestrian-seconds, or “ped-sec”) at the corner is then calculated for the same signal cycle. The ratio of net time-space divided by the pedestrian occupancy time ~~total pedestrian circulation volume per signal cycle~~ provides the LOS measurement of square feet per pedestrian (SFP).

Crosswalk LOS is also a function of time and space. Similar to the street corner analysis, crosswalk conditions are first expressed as a measurement of the available area (the crosswalk width multiplied by the width of the street) and the permitted crossing time. This measure is expressed in square feet-second. The average time required for a pedestrian to cross the street is calculated based on the width of the street and an assumed walking speed. The ratio of time-space available in the crosswalk to the total crosswalk pedestrian occupancy time is the LOS measurement of available square feet per pedestrian. The LOS analysis also accounts for vehicular turning movements that traverse the crosswalk. The LOS standards for sidewalks, corner reservoirs, and crosswalks are summarized in **Table 14-80**. The *CEQR Technical Manual* specifies acceptable LOS in Central Business District (CBD) areas is mid-LOS D or better, while acceptable LOS in non-CBD areas is within LOS C. Consistent with the traffic analysis, the CBD criteria were used in the pedestrian analyses.

Table 14-80
Level of Service Criteria for Pedestrian Elements

LOS	Sidewalks		Corner Reservoirs and Crosswalks
	Non-Platoon Flow	Platoon Flow	
A	≤ 5 PMF	≤ 0.5 PMF	> 60 SFP
B	> 5 and ≤ 7 PMF	> 0.5 and ≤ 3 PMF	> 40 and ≤ 60 SFP
C	> 7 and ≤ 10 PMF	> 3 and ≤ 6 PMF	> 24 and ≤ 40 SFP
D	> 10 and ≤ 15 PMF	> 6 and ≤ 11 PMF	> 15 and ≤ 24 SFP
E	> 15 and ≤ 23 PMF	> 11 and ≤ 18 PMF	> 8 and ≤ 15 SFP
F	> 23 PMF	> 18 PMF	≤ 8 SFP
Notes: PMF = pedestrians per minute per foot; SFP = square feet per pedestrian.

SIGNIFICANT IMPACT CRITERIA

The determination of significant pedestrian impacts considers the level of predicted deterioration in pedestrian flow or decrease in pedestrian space between the No Action and Action conditions. For different pedestrian elements, flow conditions, and area types, the CEQR procedure for impact determination corresponds with various sliding-scale formulas, as further detailed below.

Sidewalks

There are two sliding-scale formulas for determining significant sidewalk impacts. For non-platoon flow, the increase in average pedestrian flow rate (Y) in PMF needs to be greater or equal to 3.5 minus X divided by 8.0 (where X is the No Action pedestrian flow rate in PMF [$Y \geq 3.5 - X/8.0$]) for it to be a significant impact. For platoon flow, the sliding-scale formula is $Y \geq 3.03 - X/8.0$. Since deterioration in pedestrian flow within acceptable levels would not constitute a significant impact, these formulas would apply only if the With Action pedestrian flow exceeds LOS C in non-CBD areas or mid-LOS D in CBD areas. **Table 14-81** summarizes the sliding scale guidance provided by the *CEQR Technical Manual* for determining potential significant sidewalk impacts.

Table 14-81
Significant Impact Guidance for Sidewalks

Non-Platoon Flow				Platoon Flow

Corner Reservoirs and Crosswalks

The determination of significant corner and crosswalk impacts is also based on a sliding scale using the following formula: $Y \geq X/9.0 - 0.31$, where Y is the decrease in pedestrian space in SFP and X is the No Action pedestrian space in SFP. Since a decrease in pedestrian space within acceptable levels would not constitute a significant impact, this formula would apply only if the Action pedestrian space falls short of LOS C in non-CBD areas or mid-LOS D in CBD areas.

Table 14-82 summarizes the sliding scale guidance provided by the *CEQR Technical Manual* for determining potential significant corner reservoir and crosswalk impacts.

Table 14-82**Significant Impact Guidance for Corners and Crosswalks**

Sliding Scale Formula: $Y \geq X/9.0 - 0.31$			
Non-CBD Areas		CBD Areas	
No Action Pedestrian Space (X, SFP)	Action Pedestrian Space Reduction (Y, SFP)	No Action Pedestrian Space (X, SFP)	Action Pedestrian Space Reduction (Y, SFP)

I. EXISTING CONDITIONS (TRANSIT AND PEDESTRIANS)

Existing conditions for the analysis of subway station elements are based upon field surveys conducted on May 5, May 16, June 5, and June 9, 2012. Bus ridership data for the Q19, Q48, and Q66 bus routes were obtained from NYCT and the MTA Bus Company, as well as field surveys conducted on May 8, 2012. Subway ridership data were obtained from NYCT. Existing pedestrian levels are based on field surveys conducted in May and June 2012. As per the 2012 *CEQR Technical Manual*, crosswalk counts at all study area intersections were collected for one additional weekday and one additional weekend day during the representative peak periods to validate the pedestrian count data.

To determine peak conditions for transit elements and pedestrian facilities, weekday counts were conducted during the 7:00 to 9:30 AM, 11:00 AM to 1:00 PM, and 4:00 to 7:00 PM time periods for the non-game condition and 4:30 to 7:30 PM for the weekday pre-game condition. Weekend non-game counts were conducted during the 12:00 to 6:00 PM time period and weekend pre-game and post-game counts were conducted during the 2:00 to 5:00 PM and 6:00 to 8:30 PM time periods, respectively. Peak hours were determined by comparing rolling hourly averages and the highest 15-minute volumes within the selected peak hours were selected for analysis.

To determine peak conditions for bus line-haul, the most recent line-haul data were acquired for the Q48 (from NYCT), Q19 (from MTA Bus Company), and the Q66 (from MTA Bus Company)

bus routes for 2009, 2011, and 2010, respectively. A 0.5 percent annual growth rate was applied to generate the existing 2012 peak load point volumes. A ridership field survey was also conducted at the Northern Boulevard and 126th Street stop (Q19 Eastbound and Q66 Eastbound) and at the Roosevelt Avenue and 126th Street stop (Q48 Eastbound and Westbound) in May 2012. The highest hourly volumes for each route were selected for analysis.

To determine peak conditions for the subway line-haul, the 2011 subway line-haul data for the No. 7 line at the peak load points were obtained from NYCT for Manhattan-bound (40th Street-local service and Woodside and 61st Street-express service) during the AM peak hour and Flushing-bound (Queens borough Plaza-local and express service) during the PM peak hour. In order to account for the transfer of riders between the No. 7 line and the N and Q lines, a detailed line haul analysis of the N and Q lines was also conducted. Subway line-haul data for the N and Q lines at the peak load points were obtained from NYCT. The Manhattan-bound peak load point data were collected at the Queensboro Plaza station during the AM peak hour and the Queens-bound peak load point data was collected at the 59th Street/Lexington Avenue station during the PM peak hour in 2011. For a conservative estimate, maximum peak load point volumes at the 59th Street/Lexington Avenue station were applied to the Queensboro Plaza station during the PM peak hour. A 0.5 percent annual growth rate was applied to the 2011 data to generate the existing 2012 peak load point volumes for analysis. As discussed above, a detailed examination of line haul conditions on the N/Q lines will be prepared, in coordination with NYCT, for the Final EIS.

The Mets attendances on the days that the transit and pedestrian counts were performed varied; hence, adjustments of the collected data were adjusted to arrive at representative game day baseline levels for both the weekday and weekend day. On the weeknight that the transit data and the first day of pedestrian data were collected (Wednesday May 16th), Mets game attendance was 22,659, as compared to 32,587 on the second day that pedestrian crosswalk data were collected (Tuesday June 19th). The weekend game day transit data and the majority of the day one pedestrian data were collected on Saturday May 5th with the remaining day one pedestrian data collected on Saturday June 2nd. The Mets attendances on May 5th and June 2nd were 30,253 and 27,914, respectively. The second day of pedestrian crosswalk data was collected on Sunday June 17th and had a game attendance of 40,134. The second day of pedestrian crosswalk data was counted on a Sunday because there were no other Saturday 4 PM home games prior to the summer data collection moratorium and this was the only remaining applicable weekend home game. The Sunday game was a 1 PM start time and the data collection peak periods were shifted three hours earlier than the 4 PM game in order to collect comparable data with similar travel patterns.

In order to adjust existing transit and pedestrian volumes to account for conservatively representative game days, attendance data were compiled for all games from the previous two seasons (2010 and 2011). The 85th percentile attendance for weekday games for the 2010 and 2011 seasons combined was approximately 35,914 attendees and the 85th percentile attendance for weekend games for the 2010 and 2011 seasons combined was 37,577 attendees. Consistent with the traffic analysis, the first day of pedestrian and transit data were used as the baseline existing volumes prior to the 85th percentile adjustments. To adjust the existing transit and pedestrian volumes upward to the 85th percentile attendance levels, the two days of pedestrian data were compared to one another as well as the 85th percentile game day attendance numbers to determine the correlation between the increase in attendance and the increase in pedestrian volumes. As a result, a uniform growth percentage was determined per game day time period, and applied for all transit and pedestrian elements included as part of the analysis to reflect a conservatively representative 85th percentile attendance in the existing conditions. Correspondingly, the collected

transit and pedestrian volumes were grown by 33, 18, and 45 percent during the weekday pre-game, weekend pre-game, and weekend post-game peak hours, respectively.

SUBWAY STATION OPERATIONS

Since the Mets-Willets Point subway station has multiple entrances, the quantified analysis was limited to the elements that would most likely be used by riders traveling to and from Willets West, the District, and Lot B. Based on the travel demand estimates detailed in the “Traffic and Parking” section, it was determined that quantified analyses would be required for the street-level and mezzanine stairways and mezzanine ramps serving trips generated by the proposed project, as well as control areas within the subway station.

Street-level stairways on the north and south sides of Roosevelt Avenue connect to the main control area across from the station agent’s booth on the mezzanine level. Because all project-generated trips would be expected to use the street-level and street-mezzanine stairways on the north side of Roosevelt Avenue, those on the south side of Roosevelt Avenue were not analyzed. On the mezzanine level, the main control area, containing five turnstiles and one emergency exit gate, provides separation between the free and fare zones of the station. Within the fare zone, two ramps and four stairways provide access to the Manhattan-bound and Flushing-bound platforms, respectively.

On a typical day, access to and egress from the Mets-Willets Point subway station occur at the main control area. However, during several hours on game days, the main control area is disabled and the entire mezzanine level becomes a free zone to provide access to and from the passerelle, which connects the southern end of the station to the LIRR and parking south of Roosevelt Avenue, and on the north end of the station, a 42-foot wide stairway (replacing the Stadium rotunda when CitiField was completed in 2009) connects to a pedestrian plaza on the north side of Roosevelt Avenue. When this operation is in place, access to the No. 7 train is made through four individual control areas, with six to eight turnstiles each, connecting to the six platform ramps and stairways. Hence, game-day station analysis considers the condition at these four control areas instead of the main station control area.

As described in the previous section, surveys were conducted in May and June 2012 to determine peak hour pedestrian volumes at the street level stairway, mezzanine stairways and ramps, and control areas within the station and were adjusted to account for conservatively representative 85th percentile attendance. Typically, subway station elements would be evaluated for only the AM and PM commuter peak hours. However, to address worst-case game-day conditions at the Mets-Willets Point subway station, the weekday pre-game, and weekend pre-game and post-game conditions were also included for analysis.

As shown in **Tables 14-83** and **14-84**, all analyzed stairways and ramps and control areas currently operate at acceptable levels during all peak hours.

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C =Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15- Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff = Friction Factor							

SUBWAY LINE HAUL LEVELS

A subway line-haul analysis typically considers the weekday commuter period leave load levels at the analysis routes' peak load points. Because peak travel to and from the project site is expected to be westbound in the morning and eastbound in the afternoon, a line-haul capacity analysis was conducted for the No. 7 Manhattan-bound express line at the Woodside-61st Street subway station and for the No. 7 Manhattan-bound local line at the 40th Street station for the AM peak period and for the Flushing-bound trains at the Queensboro Plaza subway station for the PM peak period. In addition, based on the NYCT transit model run results, it was estimated that the transfer trips from the No.7 line to the N and the Q lines would exceed the line-haul analysis threshold of 200 riders per line per direction. Therefore, a line-haul analysis for the N and the Q lines was also prepared in accordance with 2012 CEQR Technical Manual analysis guidelines. The No. 7 subway line operates 11-car trains with a capacity of 110 passengers per car, while the N and the Q lines operate with 10-car trains with capacities of 145 passengers per car. The guideline capacity of these cars is 110 passengers each. However, crush loads could reach as many as 165 passengers per car. The 2011 Manhattan-bound and Flushing Queens-bound peak load point passenger volumes and the number of peak period trains were obtained from NYCT for No. 7 line and the N and the Q lines. Subsequent to the certification of the DSEIS, NYCT has refined the peak load point numbers (i.e., ridership volume and trains per hour) and the revised numbers have been incorporated into this Final SEIS analysis. A 0.5 percent annual growth rate was applied to generate the existing 2012 peak load point volumes. As shown in **Table 14-85**, all analyzed lines operate below guideline capacity with the exception of the No. 7 train currently operates below guideline capacity during the weekday AM commuter peak period for the Manhattan-bound local service and during the weekday PM commuter peak period for the Flushing-bound service. However, the Manhattan-bound No. 7 express service exceeds the guideline capacity during the weekday AM peak period. Between the Draft SEIS and Final SEIS, a detailed examination of line haul conditions on the N/Q lines will also be prepared, in coordination with NYCT.

Table 14-85
2012 Existing Conditions: Peak Hour Subway Line Haul

<u>Subway lines</u> Direction of Travel	Station	Trains/ Hour	Volume	Leave Load		Available Capacity
				Guideline Capacity	V/C Ratio

<u>No. 7</u> Flushing-bound Express + Local	Queensboro Plaza	24 23	20,499 <u>20,074</u>	25,410 <u>27,830</u>	0.81 <u>0.72</u>	4,911 <u>7,756</u>
<u>N line: Queens-bound</u>	<u>Queensboro Plaza¹</u>	<u>7</u>	<u>6,496</u>	<u>10,150</u>	<u>0.64</u>	<u>21,334</u>
<u>Q line: Queens-bound</u>	<u>Queensboro Plaza¹</u>	<u>7</u>	<u>5,499</u>	<u>10,150</u>	<u>0.54</u>	<u>22,331</u>
Sources: New York City Transit						
Notes:						
For the AM peak hour, although transit data show that a total of 27 trains traverse the respective express and local peak load points, the total number of scheduled trains during this hour is 26 trains.						
¹ For a conservative estimate, maximum peak load point volumes at 59th Street and Lexington Avenue station were applied to the Queensboro Plaza station.						

BUS LINE HAUL LEVELS

To assess the potential impacts on the study area bus routes, the most recent ridership data were acquired from NYCT and the MTA Bus Company. As shown in **Table 14-86**, all three routes presently operate within guideline capacities (54 passengers per bus) at their respective maximum load points. In addition, existing load levels at bus stops serving CitiField and the Willets Point area were surveyed. The Q48 makes stops along Roosevelt Avenue at 114th Street, the Mets-Willets Point subway station, and 126th Street both eastbound and westbound. The Q19 and Q66 have a stop along eastbound Northern Boulevard between 126th Street and 126th Place but no Q66 buses made stops during the field surveys. In the westbound direction, there is not a marked bus stop. However, according to the MTA Bus Company, the Q66 currently makes stops westbound at the Northern Boulevard intersection with 126th Street while the Q19 bypasses the area. The survey data summarized in **Table 14-87** show that the eastbound Q19 and Q66 passenger loads at the Northern Boulevard and 126th Street stop are lower than those at the two routes' respective maximum load points. Therefore, load levels at the area wide maximum load points shown in **Table 14-86** were conservatively used for the analysis of the Q19 and Q66 routes. For the Q48, because the incremental bus passenger volumes generated by the proposed project are expected to shift the route's maximum load points to the Mets-Willets Point subway station bus stops even though the existing passenger loads at the Roosevelt Avenue and 126th Street stops are lower than those at the route's maximum load points during peak hours, the future conditions analyses for this route would consider changes only at the bus stops serving the project site.

Table 14-86

2012 Existing Conditions: Bus Line Haul at NYCT Maximum Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound

STREET-LEVEL PEDESTRIAN OPERATIONS

The study area sidewalks, corner reservoirs, and crosswalks were assessed for the weekday AM, midday, PM, and pre-game peak periods, as well as, the weekend midday non-game, pre-game, and post-game peak periods. As discussed earlier, in accordance with the 2012 *CEQR Technical Manual*, a second day of count data was collected for all the crosswalks included in the pedestrian analysis for all time periods to develop the existing peak hour pedestrian volumes. The existing peak hour pedestrian volumes are shown in **Appendix D**.

As shown in **Tables 14-88** through **14-92**, all sidewalk, corner reservoir, and crosswalk analysis locations operate at acceptable levels (maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners and crosswalks), except at the following locations:

- The north crosswalk of 34th Avenue and 126th Street, which operates at LOS F with 5.3 SFP during the weekend post-game peak 15-minute period.
- The south crosswalk of 34th Avenue and 126th Street, which operates at LOS E with 11.4 SFP during the weekend post-game peak 15-minute period.

J. THE FUTURE WITHOUT THE PROPOSED PROJECT (TRANSIT AND PEDESTRIANS)

Transit and pedestrian conditions in the future without the proposed project were assessed to establish future baseline conditions or the “No Action” condition against which to evaluate the potential project impacts. The No Action analyses, prepared for the 2018, 2028, and 2032 analysis years, incorporate background growth, new trips associated with nearby developments, and changes in the transportation environment that would affect transit service and pedestrian movements in the study area.

2018 NO ACTION CONDITION

TRANSIT AND PEDESTRIAN VOLUME PROJECTIONS

Estimates of peak hour transit and pedestrian volumes in the No Action condition were developed by applying the CEQR-recommended 0.50 percent annual background growth rate for the first five years (year 2012 to year 2017) and then 0.25 percent for the remaining year (year 2017 to year 2018) onto existing transit and pedestrian volumes and by adding the estimated transit and pedestrian volumes generated by projects within and near the study area that would be completed independent of the proposed project.

As discussed in Chapter 2, “Land Use, Zoning, and Public Policy,” numerous projects located near the project site are expected to be completed by 2018 independent of the proposed project. The transit and pedestrian analysis considers projects expected to be developed in the future without the proposed project, as shown in **Figure 14-3**. However, because the project site is geographically separated from these No Action projects by the adjacent highway network, new trips associated with these projects would have limited effects on most of the study area transit and pedestrian elements. Therefore, as detailed further below, these trips are accounted for differently in each of the specific analyses.

SUBWAY STATION OPERATIONS

The same station elements previously analyzed for existing conditions were analyzed under the 2018 No Action condition. Pedestrian volumes were adjusted to 2018 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 for the remaining year for an overall compounded growth rate of approximately 2.8 percent by 2018. Because all No Action projects are not in the immediate vicinity of the project site, they are not expected to generate trips within the project site or using the Mets-Willeys Point subway station. **Table 14-93** details the operating conditions for stairways and ramps while **Table 14-94** details operating conditions at control areas within the station in the future 2028 No Action condition. As shown, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels during all peak hours.

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C = Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15- Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff = Friction Factor							

SUBWAY LINE HAUL LEVELS

Subway ridership numbers were also adjusted to 2018 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 percent for the remaining year.

No. 7 Line

~~Furthermore, trips associated with major new developments along the No. 7 subway line were superimposed onto~~ added to the 2018 background line-haul volumes to generate No Action peak period volumes for the No. 7 line subway line-haul analysis. Subway trips generated by No Action projects in Corona and Flushing were distributed directionally in a similar manner as subway trips generated by the proposed project due to the proximity of these neighborhoods to the project site. Because the Flushing-Main Street subway station is the No. 7 subway line's eastern terminus, all trips generated by No Action projects in that area were assigned to the Manhattan-bound direction in the AM peak period and the Flushing-bound direction in the PM peak period. These trips include several large and small projects planned for the Flushing area. Although a small number of trips from the No Action projects in Corona could travel in the off-peak direction, to/from Flushing, it was conservatively assumed that all of these trips would also travel in the peak direction during both the AM and PM peak periods.

In addition, NYCT plans to add two trains to the peak direction for both the AM and PM peak periods. Compared with the 2012 existing conditions, the 2018 No Action subway line-haul volumes are expected to increase by approximately 5 percent in the Manhattan-bound direction during the AM peak hour and 6 percent in the Flushing-bound direction during the PM peak hour. As shown in **Table 14-95**, assuming that planned service improvements are implemented, the No. 7 line would operate within guideline capacity during the weekday AM peak period for the Manhattan-bound local service and during the weekday PM peak period for the Flushing-bound service. However, the Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2018 No Action condition. ~~Between the Draft SEIS and Final SEIS, a detailed examination of line-haul conditions on the N/Q lines will also prepared, in coordination with NYCT.~~

N and Q Lines

Based on NYCT transit demand model estimates, approximately 19 percent of the No Action project generated subway riders who take the No.7 train to/from Queens would make a transfer to the N and the Q lines at the Queensboro Plaza station.

According to NYCT's estimate, the N and Q lines' ridership levels would increase by approximately 19.5 percent from 2011 to 2033 largely due to the planned developments in Astoria, Queens. Although this growth rate accounts for the 22 years of background growth, this rate was applied to the 2018 No Action condition and carried forward for the 2028 and 2032 No Action conditions to conservatively estimate the No Action ridership. Additionally, after the completion of Phase 1 of the Second Avenue subway, the Q line will be rerouted to serve the 2nd Avenue line and an alternate service will be provided to replace the service in Astoria (tentatively assigned as the "W" line). As mentioned above, approximately 19 percent of the No.7 line riders to/from Queens would transfer to the N and Q lines at the Queensboro Plaza station. These transfer riders would be added to the each of the No Action baseline volumes (2018, 2028, and 2032) on the N and Q lines. It was assumed that the transfer riders would be equally distributed on the N and the Q lines. As shown in **Table 14-95**, while the N and Q lines would continue to operate within the guideline capacity during the PM peak hour for Queens-bound service, both lines would exceed the guideline capacity during the AM peak hour for Manhattan-bound service.

Table 14-95
2018 No Action Condition: Peak Hour Subway Line Haul

Q (W) Queens-bound ¹	Queensboro Plaza	7	6,677	10,150	0.66	3,473
Notes: For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains. ¹ <u>W</u> is a tentative designation for a line that would replace the Q service in Queens. Source: New York City Transit						

BUS LINE HAUL LEVELS

The 2018 No Action condition analysis of bus line-haul levels incorporates annual growth rates on the three study area bus routes as mentioned above by applying a 0.50 percent for the first five years and a 0.25 percent for the remaining year. Since there is an abundance of bus routes serving the many development projects planned for the Flushing area, the incorporation of only the background growth is expected to be adequate in accounting for potential increases in ridership on the three study area bus routes absent the proposed project. The No Action analysis results are presented in **Table 14-96**. As shown, all three bus routes would continue to operate within the guideline capacity during the AM and PM peak periods.

Table 14-96
2018 No Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound

Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

STREET-LEVEL PEDESTRIAN OPERATIONS

Since new trips associated with the No Action projects are not expected to traverse the study area analysis locations, the 2018 No Action pedestrian volumes incorporate only an annual background growth rate of 0.50 percent for the first five years and 0.25 for the remaining year for an overall compounded growth rate of approximately 2.8 percent. The 2018 No Action peak hour pedestrian volumes are shown in **Appendix D**. As shown in **Tables 14-97** through **14-101**, all sidewalk, corner reservoir, and crosswalk analysis locations would continue to operate at acceptable

Willeys Point Development

levels (maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners and crosswalks), except at the following locations:

- The north crosswalk of 34th Avenue and 126th Street, which would operate at LOS F with 4.9 SFP during the weekend post-game peak 15-minute period.
- The south crosswalk of 34th Avenue and 126th Street, which would operate at LOS E with 10.8 SFP during the weekend post-game peak 15-minute period.

Notes: SFP = square feet per pedestrian.

N/A = Crosswalk volume is zero, and SFP is not calculable. LOS is assumed to be A.

2028 NO ACTION CONDITION

TRANSIT AND PEDESTRIAN VOLUME PROJECTIONS

Estimates of peak hour transit and pedestrian volumes in the No Action condition were developed by applying the CEQR-recommended 0.50 percent annual background growth rate for the first five years (year 2012 to year 2017) and then 0.25 percent for the remaining eleven years (year 2017 to year 2028) onto existing transit and pedestrian volumes and by adding the estimated transit and pedestrian volumes generated by projects within and near the study area that would be completed independent of the proposed project, as described above under “2018 No Action Condition.”

SUBWAY STATION OPERATIONS

The same station elements previously analyzed for existing conditions were analyzed under the 2028 No Action condition. Pedestrian volumes were adjusted to 2028 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 for the remaining years for an overall compounded growth rate of approximately 5.4 percent by 2028. **Table 14-102** details the operating conditions for stairways and ramps while **Table 14-103** details operating conditions at control areas within the station in the future 2028 No Action condition. As shown, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels during all peak hours.

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C =Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15- Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff = Friction Factor							

SUBWAY LINE HAUL LEVELS

The No. 7 line subway ridership numbers were also adjusted to 2028 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 for the remaining years, and incorporating trips associated with projected No Action projects, as described under “2018 No Action Condition.” As shown in **Table 14-104**, the No. 7 line would operate within guideline capacity during the weekday AM peak period for the Manhattan-bound local service and during the PM peak period for the Flushing-bound service. However, the No. 7 Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2028 No Action condition. ~~Between the Draft SEIS and Final SEIS, a detailed examination of line haul conditions on the N/Q lines will also prepared, in coordination with NYCT. As described under “2018 No Action Condition,” the estimated 19.5 percent background growth was applied to the 2028 No Action analysis to account for the No Action project generated subway riders on the N and Q lines. As shown in Table 14-104, the N and Q lines would continue to operate within the guideline capacity during the PM peak hour for Queens-bound service while both lines would continue to exceed the guideline capacity during the AM peak hour for Manhattan-bound service.~~

Table 14-104

2028 No Action Condition: Peak Hour Subway Line Haul

<u>Subway lines</u> Direction of Travel	Station	Trains/ Hour	Volume	Leave Load		Available Capacity
				Guideline Capacity	V/C Ratio	
AM Peak Period						
<u>No. 7</u> Manhattan-bound Express	Woodside–61st Street	45 14	49,900 17,677	48,450 16,930	1.10 1.04	-1,750 -737
<u>No. 7</u> Manhattan-bound Local	40th Street	14	45,598 13,757	16,940	0.92 0.81	1,342 3,183
<u>N</u> Manhattan-bound	<u>Queensboro Plaza</u>	8	13,504	11,600	1.16	-1,904
<u>Q (W)</u> Manhattan-bound ¹	<u>Queensboro Plaza</u>	8	12,777	11,600	1.10	-1,177
PM Peak Period						
<u>No. 7</u> <u>Queens</u> -bound Express + Local	Queensboro Plaza	23 25	22,550 22,102	27,830 30,250	0.81 0.73	5,280 8,148
<u>N</u> <u>Queens</u> -bound	<u>Queensboro Plaza</u>	7	7,869	10,150	0.78	2,281
<u>Q (W)</u> <u>Queens</u> -bound ¹	<u>Queensboro Plaza</u>	7	6,677	10,150	0.66	3,473
Notes: For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains. ¹ <u>W</u> is a tentative designation for a line that would replace the Q service in Queens.						
Sources: New York City Transit						

BUS LINE HAUL LEVELS

The 2028 No Action condition analysis of bus line-haul levels incorporates annual growth rates on the three study area bus routes as mentioned above by applying a 0.50 percent for the first-5 five years and a 0.25 percent for the remaining years. The No Action analysis results are presented in **Table 14-105**. As shown, all three bus routes would continue to operate within the guideline capacity during the AM and PM Peak periods.

Table 14-105

2028 No Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound	
			Load Point	AP		Load Point	AP

	PM	5	Roosevelt at 126th	22	5	Roosevelt at 126th	23
Q66 (to Woodside and LIC)	AM	15	Northern Blvd/ 110th St	48	14	Northern Blvd/ 72nd St	47
	PM	10	Northern Blvd/ 110th St	21	10	Northern Blvd/ 106th St	21
Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

STREET-LEVEL PEDESTRIAN OPERATIONS

As described above under “2018 No Action Condition,” since new trips associated with the No Action projects are not expected to traverse the study area analysis locations, the 2028 No Action pedestrian volumes incorporate only an annual background growth rate of 0.50 percent for the first five years and 0.25 percent for the remaining years for an overall compounded growth rate of approximately 5.4 percent. The 2028 No Action peak hour pedestrian volumes are shown in **Appendix D**. As shown in **Tables 14-106** through **14-110**, all sidewalk, corner reservoir, and crosswalk analysis locations would continue to operate at acceptable levels (maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners and crosswalks), except at the following locations:

Willeys Point Development

- The north crosswalk of 34th Avenue and 126th Street, which operates at LOS F with 4.5 SFP during the weekend post-game peak 15-minute period.
- The south crosswalk of 34th Avenue and 126th Street, which operates at LOS E with 10.2 SFP during the weekend post-game peak 15-minute period.

2032 NO ACTION CONDITION

TRANSIT AND PEDESTRIAN VOLUME PROJECTIONS

Estimates of peak hour transit and pedestrian volumes in the No Action condition were developed by applying the CEQR-recommended 0.50 percent annual background growth rate for the first five years (year 2012 to year 2017) and then 0.25 percent for the remaining fifteen years (year 2017 to year 2032) onto existing transit and pedestrian volumes and by adding the estimated transit and pedestrian volumes generated by projects within and near the study area that would be completed independent of the proposed project, as described above under “2018 No Action Condition.”

SUBWAY STATION OPERATIONS

The same station elements previously analyzed for existing conditions were analyzed under the 2032 No Action condition. Pedestrian volumes were adjusted to 2032 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 percent for the remaining years for an overall compounded growth rate of approximately 6.4 percent by 2032. **Table 14-111** details the operating conditions for stairways and ramps while **Table 14-112** details operating conditions at control areas within the station in the future 2032 No Action condition. As shown, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels during all peak hours.

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C = Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15-Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff = Friction Factor							

SUBWAY LINE HAUL LEVELS

The No.7 line subway ridership numbers were also adjusted to 2032 levels using an annual background growth rate of 0.50 percent for the first five years and then 0.25 percent for the remaining years, and incorporating trips associated with projected No Action projects, as described under “2018 No Action Condition.” As shown in **Table 14-113**, the No. 7 line would operate within guideline capacity during the weekday AM peak period for the Manhattan-bound local service and during the PM peak period for the Flushing-bound service. However, the Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2032 No Action condition. ~~Between the Draft SEIS and Final SEIS, a detailed examination of line-haul conditions on the N/Q lines will also prepared, in coordination with NYCT.~~

As described under “2018 No Action Condition,” the estimated 19.5 percent background growth rate was applied to the 2032 No Action analysis to account for the No Action project generated subway riders on the N and Q lines. As shown in Table 14-113, the N and Q lines would continue to operate within the guideline capacity during the PM peak hour for Queens-bound service while both lines would continue to exceed the guideline capacity during the AM peak hour for Manhattan-bound service.

Table 14-113

Sources: New York City Transit						
Notes:						
For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains.						
¹ <u>W</u> is a tentative designation for a line that would replace the Q service in Queens.						

BUS LINE HAUL LEVELS

The 2032 No Action condition analysis of bus line-haul levels incorporates annual growth rates on the three study area bus routes as mentioned above by applying a 0.50 percent for the first-5 five years and a 0.25 percent for the remaining years. The No Action analysis results are presented in **Table 14-114**. As shown, all three bus routes would continue to operate within the guideline capacity during the AM and PM peak periods.

Table 14-114

2032 No Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound	
			Load Point	AP		Load Point	AP

	PM	10	Northern Blvd/ 110th St	21	10	Northern Blvd/ 106th St	21
Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

STREET-LEVEL PEDESTRIAN OPERATIONS

As described above under “2018 No Action Condition,” since new trips associated with the No Action projects are not expected to traverse the study area analysis locations, the 2032 No Action pedestrian volumes incorporate only an annual background growth rate of 0.50 percent for the first five years and 0.25 percent for the remaining years for an overall compounded growth rate of approximately 6.4 percent. The 2032 No Action peak hour pedestrian volumes are shown in **Appendix D**. As shown in **Tables 14-115** through **14-119**, all sidewalk, corner reservoir,

Willeys Point Development

and crosswalk analysis locations would continue to operate at acceptable levels (maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners and crosswalks), except at the following locations:

- The north crosswalk of 34th Avenue and 126th Street, which operates at LOS F with 4.4 SFP during the weekend post-game peak 15-minute period.
- The south crosswalk of 34th Avenue and 126th Street, which operates at LOS E with 10.0 SFP during the weekend post-game peak 15-minute period.

K. PROBABLE IMPACTS OF THE PROPOSED PROJECT (TRANSIT AND PEDESTRIANS)

The future with the proposed project or the “With Action” condition would result in increased transit and pedestrian volumes within the study area. This section describes the projected travel patterns of the site-related trips and assesses their potential impacts on nearby transit and pedestrian facilities for the 2018, 2028, and 2032 analysis years. Where significant adverse impacts are identified, measures to mitigate the impacts are described in Chapter 21, “Mitigation.”

2018 WITH ACTION CONDITION

TRIP DISTRIBUTION AND ASSIGNMENT

Transit and pedestrian volumes for the With Action condition were estimated by overlaying peak hour volumes derived from the trip generation estimates presented in the “Traffic and Parking” section, onto the No Action analysis networks. These volumes were then assigned to the transit and pedestrian analysis locations based on the following assumptions.

- Automobile and taxi person trips associated with the District are expected to have a negligible effect on the pedestrian network, since both would be dispersed throughout the District east of 126th Street, and the associated pedestrian trips, which would mostly occur in the District itself, would traverse a limited number of the pedestrian elements included for analysis. The Willets West development would have an on-site parking garage for autos and a designated taxi drop-off/pick-up area, and therefore, no auto and taxi trips associated with Willets West would traverse any of the pedestrian elements included for analysis. As part of the Willets West development, approximately 3,700 existing CitiField parking spaces would be displaced from the current CitiField parking lot. Specific to Phase 1A, 2,750 of the displaced spaces would be constructed in an interim surface parking lot within the District, with the remaining displaced spaces to be replaced in a new CitiField garage, south of Roosevelt Avenue, within the current “South Lot.” The CitiField patrons who in Phase 1A would park in the District’s interim parking lot would then need to cross 126th Street to access the stadium. It was assumed that half of the patrons would cross 126th Street at 37th Avenue with the other half would cross at 38th Avenue. The patrons who would park in the new South Lot garage would connect with CitiField via the Mets-Willets Point subway station, as they do currently during game days, and would not traverse any of the pedestrian elements included for analysis. It should be noted that NYCT may ultimately decide to revert back to its pre-CitiField station operating plan. Under this operating plan, the station would function during Met games as it would on non-game days—the wider portion of the mezzanine, which is within the paid zone on most occasions but currently is converted to an unpaid zone during games would be kept as a part of the paid zone at all times. The unpaid corridor at the western end of the mezzanine would remain unpaid at all times and thus could serve as a means of crossing Roosevelt Avenue through the station. If this plan is implemented, NYCT would reposition the agent booth in the unpaid zone to provide added circulation space in the corridor.
- Subway trips were assigned to the Mets-Willets Point subway station. The assignments to specific stairways were based on logical patterns between the subway station and Willets West and the District.

- Based on existing ridership patterns, bus trips were assigned to the study area bus routes as follows: 15 percent to the Q19, 70 percent to the Q66, and 15 percent to the Q48 bus routes. Assignments on these bus routes were made with logical origins and destinations. This allocation of projected bus trips conservatively does not assume other service improvements, such as new bus routes or extension of existing bus routes, that are typical with areas undergoing substantial growth in ridership from new developments. As stated in the FGEIS, discussions were initiated with the MTA to explore opportunities to extend existing bus routes from adjacent neighborhoods (e.g., downtown Flushing) and/or creating new bus routes. Potential bus service improvements discussed include: 1) increasing service frequency on the Q19 and providing westbound stop/loop service to Willets Point; 2) extending some or all bus routes that currently terminate in downtown Flushing to Willets Point, including the Q12, Q13, Q15/Q15A, Q16, Q26, and Q28; and 3) possibly extending the limited Q50 along Roosevelt Avenue through Willets Point. These potential service improvements would require new bus stops and layover areas in and around the project site. Between the Draft and Final SEIS, additional discussions were initiated with MTA NYCT regarding the potential bus service improvements discussed above. MTA NYCT considered the Q19 westbound loop to serve Willets West and the District to be unfavorable due to its circuitous routing. The MTA Bus Company would consider extending the Q50 and NYCT would consider extending one of the current bus routes terminating in downtown Flushing to Willets West and the District initially. Additional bus route extensions to Willets West and the District would be considered based on future demand. In addition, several conceptual bus routing options were explored to provide the necessary layover areas and stop locations for the potential bus route extensions. MTA NYCT has found the conceptual bus routing options to be generally reasonable and feasible. While no definitive plans have been made at this time, the City and the applicant will continue to collaborate with the MTA NYCT during and after this environmental review process to ensure that adequate bus service improvements would be implemented, no definitive plans have been made at this time.
- Walk-only trips, primarily within the District, were evenly distributed to the surrounding street network. Even though the majority of the future uses within the District would not be developed yet in Phase 1A, the walk only trips were conservatively distributed to the street network, assuming a higher percentage of trips originating from Corona and Flushing. As part of the later phases, a higher percentage of walk only trips would be generated by other uses within the District, resulting in an increased internal trip capture percentage and a lower percentage of trips originating from Corona and Flushing. As a result of the increased internal capture percentage, a high number of walk only trips generated by uses within the District would not appear on any of the pedestrian elements included for analysis. As for the walk-only trips that would be generated by the Willets West development, all were distributed to the street network, including a portion assumed to originate from or destined to future uses in the District, and no internal capture was assumed. Since the Willets West development would already be developed in Phase 1A and included in the two subsequent phases, the trip distribution remained consistent for all phases. Unlike the uses within the District, however, the percentage of walk-only trips originating from Corona and Flushing would be consistent for all three phases.

CHANGES IN THE PEDESTRIAN ENVIRONMENT

The 2018 With Action condition pedestrian analysis reflects geometric changes to crosswalk lengths, sidewalk widths, and corner dimensions consistent with those outlined in the FGEIS. Specific geometric changes affecting the analysis elements include:

- Modifying 126th Street to serve as the main entryway to the District, resulting in enlarged pedestrian circulation areas on sidewalks on the east side of the street and a new bicycle path on both sides of the street;
- Constructing new streets within the District, resulting in different crossing distances and sidewalk widths from the No Action condition; and
- As part of the project's overall plan of developing Willets West and moving the majority of Mets parking to the south side of Roosevelt Avenue, pedestrian plazas would form within what are currently enclosed parking areas for the Mets. These pedestrian plazas would provide additional means of pedestrian circulation adjacent to Willets West and CitiField.

SUBWAY STATION OPERATIONS

The same station elements previously analyzed for the existing and No Action conditions were analyzed under the With Action condition. Project-generated subway trips were added to the 2018 No Action volumes to generate the 2018 With Action volumes for the analysis of station operations. It was assumed that all incremental subway trips would access the Mets-Willets Point subway station via the street-level and street-mezzanine stairways on the north side of Roosevelt Avenue. Once inside the station, these trips were distributed to the Manhattan-bound and Flushing-bound platforms using the directional split developed for the subway line-haul analysis, as detailed in the next sub-section. Passenger movements between the mezzanine and platform levels were distributed based on existing flow patterns during the various analysis time periods.

As shown in **Tables 14-120** and **14-121**, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels. Therefore, the proposed project would not result in any significant adverse subway station impacts under the 2018 With Action condition. However, as described above, if NYCT reverts back to its pre-CitiField station operating plan, whereby passage through the station between parking in South Lot/Lot D and the north side of Roosevelt Avenue could be made only within the unpaid zone, additional impacts for the station's street-level connections and the unpaid zone passageway could occur during game days. Because game-day conditions occur on average only approximately 80 ~~40 to 50~~ times a year and are subject to game-day traffic and pedestrian management, such impacts would be intermittent and may not require permanent mitigation measures. Furthermore, since the planning and design of this station reconfiguration has not yet taken place, the specific nature of the potential game-day impacts cannot be ascertained and any mitigation measures that may be deemed feasible to address the potential game-day impacts also cannot be identified at this time. If NYCT decides to proceed with this station reconfiguration, which would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day management strategies. For purposes of disclosure in this Final Draft SEIS, any impacts that may be attributed to future passage of a reconfigured Mets-Willets Point subway station may potentially be deemed unmitigatable.

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C =Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15- Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff = Friction Factor							

SUBWAY LINE HAUL LEVELS

Trips associated with the proposed project were ~~superimposed onto~~ added to the No Action line-haul volumes to generate the With Action peak period volumes for the subway line-haul analysis. Census data were reviewed to estimate directional travel patterns between Willets Point and Flushing and with various locations to the west. Ratios and trip distribution patterns of current subway trips originating in the area near the project site were developed based on information provided by NYCT, as summarized in **Table 14-122**. Although there are various uses planned for the District and Willets West, subway trip-making patterns during the commuter peak hours are likely to be similar for all uses. Hence, this set of trip distribution patterns was used for assigning all AM and PM peak hour project-generated subway trips to different segments of the No. 7 subway line.

Table 14-122
Distribution of Willets West and District Subway Trips

No. 7 Train Load	Percent of Total Trips
<i>Westbound Trips (from District)</i>	
Transfer to E/F/M/R	6%
Express Line-Haul @ Woodside	73%
Local Line-Haul @ 40th Street	12%
Transfer to SB N/Q @ Queensboro Plaza	19%
Transfer to SB 4/5 @ Grand Central	10%
Transfer to SB 6 @ Grand Central	6%
<i>Eastbound Trips (to District)</i>	
Transfer from NB 6 @ Grand Central	6%
Transfer from NB 4/5 @ Grand Central	10%
Transfer from NB N/Q @ Queensboro Plaza	19%
Combined Line-Haul East of Queensboro Plaza	85%
Transfer from E/F/M/R	6%
Sources: NYCT	

The projected peak hour subway trip increments at the peak load points for the No. 7, ~~the N, and the Q~~ subway lines, were superimposed onto added to the respective No Action line-haul volumes. As shown in **Table 14-123**, ~~with the overlay of these project-generated trips,~~ the No. 7 subway line would continue to operate within guideline capacity during the AM peak period for the Manhattan-bound local service and during the PM peak period for the Flushing-bound service. As with the 2018 No Action condition, the Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2018 With Action condition. On average, the project-generated subway trips would add one passenger per car to the Manhattan-bound express line at the peak load point during the AM peak period, which is less than the *CEQR Technical Manual* impact threshold of five passengers per car. Hence, Phase 1A of the proposed project would not result in a significant adverse line-haul impact on the No. 7 line.

~~In addition, because NYCT expects that there would be notable transfer activities between the No. 7 line and the N/Q lines at the Queensboro Plaza subway station (across the platform transfers), a detailed examination of line-haul conditions on the N/Q lines will be prepared, in coordination with NYCT, for the Final EIS. However, since the estimated Phase 1A project-generated increments would be fewer than 5 persons per subway car (up to 108 passengers in 120 to 130 train cars) on the N/Q trains, Phase 1A of the proposed project would similarly not result in a significant adverse line-haul impact on the N/Q lines.~~

The N and the Q lines would continue to operate within guideline capacity during the PM peak hour. As with 2018 No Action condition, the N and the Q lines would continue to exceed the guideline

capacity during the weekday AM peak period under the 2018 With Action condition. On average, the project-generated subway trips would add one passenger per car to each of the N and the Q lines at the peak load point during the AM peak period, which is fewer than the *CEQR Technical Manual* impact threshold of five passengers per car. Therefore, Phase 1A (2018) of the proposed project would not result in a significant adverse line-haul impact on the N and the Q lines.

Table 14-123
2018 With Action Condition: Peak Hour Subway Line Haul

<u>Subway Lines</u> Direction of Travel	Station	Trains /Hour	Volume	Leave Load		Available Capacity
				Guideline Capacity	V/C Ratio

<u>No. 7</u> Flushing-bound Express + Local	Queensboro Plaza	23 25	22,503 22,066	27,830 30,250	0.81 0.73	5,327 8,184
<u>N</u> Queens-bound	<u>Queensboro Plaza</u>	7	7,923	10,150	0.78	2,227
<u>Q (W)</u> Queens-bound ¹	<u>Queensboro Plaza</u>	7	6,731	10,150	0.66	3,419
Sources: New York City Transit						
Notes:						
For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains.						
¹ W is a tentative designation for a line that would replace the Q service in Queens.						

BUS LINE HAUL LEVELS

As discussed above, although there would potentially be other bus routes serving the project site once development components of the proposed project are completed and occupied, the 2018 With Action analysis of potential bus line-haul impacts considers only the bus routes and stops that exist currently. Peak hour bus ridership levels were estimated by adding the incremental trips associated with the proposed project to bus stop locations along Roosevelt Avenue at 126th Street for the Q48 and to maximum load points along the Q19 and Q66. It was estimated that 40 to 60 percent of the bus trips would originate from Corona and the remaining 40 to 60 percent from Flushing. Bus trip assignments were divided into trips coming into and departing from Willets West and the District as follows:

- Into the project site traveling eastbound from Corona
 - 45 to 50 percent would take the Q48 along Roosevelt Avenue;
 - 45 to 50 percent would take the Q19 along Northern Boulevard; and
 - 70 to 75 percent would take the Q66 along Northern Boulevard.
- Into the project site traveling westbound from Flushing
 - 45 to 50 percent would take the Q48 along Roosevelt Avenue; and
 - 85 to 90 percent would take the Q66 along Northern Boulevard (As discussed, according to the MTA Bus Company, the westbound Q19 does not make a stop within the study area; therefore, no westbound trips were assigned to this route.).
- Out from the project site traveling westbound to Corona

- 18 percent would take Q48 along Roosevelt Avenue (this includes 9 percent that would transfer to Q19 outside the study area); and
- 42 percent would take Q66 along Northern Boulevard.
- Out from the project site traveling eastbound to Flushing
 - 6 percent would take Q48 along Roosevelt Avenue;
 - 28 percent would take Q66 along Northern Boulevard; and
 - 6 percent would take Q19 along Northern Boulevard.

As described above, impacts to bus line-haul levels would be considered significant if a proposed action would result in operating conditions above guideline capacities. As shown in **Table 14-124**, all three bus routes would continue to operate within guideline capacity (54 passengers per bus) during the AM and PM peak period under the 2018 With Action condition. Hence, Phase 1A of the proposed project would not result in a significant adverse impact on bus line-haul conditions.

Table 14-124

2018 With Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound	
			Load Point	AP		Load Point	AP

	PM	10	Northern Blvd/ 110th St	48	10	Northern Blvd/ 106th St	50
Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

STREET-LEVEL PEDESTRIAN OPERATIONS

As described above under “Changes in the Pedestrian Environment,” the east side of 126th Street would be developed with larger pedestrian circulation areas. In accordance with the District’s design guidelines, the at-grade sidewalks would be at least 15 feet wide. Adjacent to these sidewalks would be plazas of 20 to 35 feet wide. These plazas would provide additional outdoor activity areas and serve as transitions to the building façade and entrances located several feet above grade. Based on current illustrative designs of these pedestrian circulation areas, the at-grade sidewalks are expected to provide a minimum clear path of 10 feet while the elevated plazas would provide a minimum clear path of 8 feet. Since pedestrians are expected to use both pedestrian areas to traverse the east side of 126th Street, the analyses presented herein conservatively accounted for an effective “sidewalk” width of 10 feet within the cumulative 18 feet of clear path.

In addition, related pedestrian analyses were prepared for the three intersections (126th Street at 36th Avenue, 126th Street at 37th Avenue, and Northern Boulevard at 126th Place) where additional traffic analyses were conducted and presented in this Final SEIS.

The study area sidewalks, corner reservoirs, and crosswalks were assessed for the weekday AM, midday, PM, and pre-game peak periods, as well as, the weekend midday non-game, pre-game, and post-game peak periods by superimposing project-generated trips onto the No Action pedestrian analysis networks. The 2018 With Action peak hour pedestrian volumes are shown in

Appendix D. As shown in **Tables 14-125** through **14-127**, all sidewalks and corner reservoirs would continue to operate at acceptable levels (within mid-LOS D, with a maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners) or incur degradations that, when compared to the No Action condition, do not exceed the *CEQR Technical Manual* sliding scale impact thresholds (See **Tables 14-81** and **14-82**). However, as shown in **Tables 14-128** and **14-129**, several study area crosswalks would operate beyond mid-LOS D (less than 19.5 SFP) and incur degradations that, when compared to the No Action condition, would exceed the *CEQR Technical Manual* sliding scale impact thresholds. These significant adverse pedestrian impacts are detailed below. Measures that can potentially mitigate these impacts are discussed in Chapter 21; “Mitigation.”

Northern Boulevard and 126th Street

- The east crosswalk would deteriorate to beyond mid-LOS D (15.6 SFP) from a No Action LOS A (5699.3 SFP), LOS E (14.0 SFP) from a No Action LOS A (5584.8 SFP), beyond mid-LOS D (16.1 SFP) from a No Action LOS A (625.9 SFP), LOS E (11.7 SFP) from a No Action LOS A (1695.1 SFP), LOS E (14.7 SFP) from a No Action LOS A (1095.3 SFP), and to LOS E (10.7 SFP) from a No Action LOS A (136.4 SFP) during the weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

Roosevelt Avenue and 126th Street

- The west crosswalk would deteriorate to LOS F (-67.6 SFP) from a No Action LOS A (194.6 SFP) during the weekend post-game peak period.

34th Avenue and 126th Street

- The north crosswalk would deteriorate to beyond mid-LOS D (17.9 SFP) from a No Action LOS A (2714.0 SFP) during the weekend non-game peak period.
- The south crosswalk would deteriorate to beyond mid-LOS D (16.5 SFP) from a No Action LOS A (5848.7 SFP), beyond mid-LOS D (18.1 SFP) from a No Action LOS A (3183.4 SFP), LOS E (11.8 SFP) from a No Action LOS A (1217.7 SFP), and to LOS E (14.1 SFP) from a No Action LOS D (23.0 SFP) during the weekday midday, weekday PM, weekend midday non-game, and weekend pre-game peak periods, respectively.
- The east crosswalk would deteriorate to LOS E (10.4 SFP) from a No Action LOS A (80.0 SFP), LOS E (14.3 SFP) from a No Action LOS A (820.4 SFP), and to LOS E (11.4 SFP) from a No Action LOS A (9927.5 SFP) during the weekday pre-game, weekend midday non-game, and weekend pre-game peak periods, respectively.

37th Avenue and 126th Street

- The north crosswalk would operate at LOS E (8.2 SFP), LOS E (8.6 SFP), and LOS D (18.4 SFP) during the weekday pre-game, weekend pre-game, and weekend post-game peak periods, respectively.
- The south crosswalk would operate at LOS E (8.6 SFP) and LOS E (9.3 SFP) during the weekday pre-game and weekend pre-game peak periods, respectively.

The significant adverse pedestrian impacts detailed above for the 2018 analysis year are summarized in **Table 14-130**.

	S Crosswalk				X		X	

Notes: X = Significantly Impacted

2028 WITH ACTION CONDITION

TRIP DISTRIBUTION AND ASSIGNMENT

Transit and pedestrian volumes for the 2028 With Action condition were estimated by overlaying peak hour volumes derived from the trip generation estimates presented in the “Traffic and Parking” section onto the No Action analysis networks. These volumes were then assigned to the transit and pedestrian analysis locations based on the following assumptions.

- As detailed above under “2018 With Action Condition,” automobile and taxi person trips associated with the District are expected to have a negligible effect on the pedestrian network, since both would be dispersed throughout the District east of 126th Street, and the associated pedestrian trips, which would mostly occur in the District itself, would traverse a

limited number of the pedestrian elements included for analysis. The Willets West development would have an on-site parking garage for autos and a designated taxi drop-off/pick-up area, and therefore, no auto and taxi trips associated with Willets West would traverse any of the pedestrian elements included for analysis. Prior to or during the development of Phase 1B uses in the District, the 2,750-space interim surface parking lot constructed in Phase 1A would be eliminated and replaced by two additional CitiField parking garages south of Roosevelt Avenue, within the current South Lot and Lot D. Therefore, the CitiField patrons who would park within the interim surface parking lot in the District in Phase 1A would instead park within South Lot/Lot D and no longer need to traverse the pedestrian study area in Phase 1B. As in Phase 1A, CitiField patrons who park in the new South Lot/Lot D garages would connect with CitiField via the Met-Willets Point subway station, as they do currently during game days, and would not traverse any of the pedestrian elements included for analysis. As noted for the 2018 With Action analysis, NYCT may ultimately decide to revert back to its pre-CitiField station operating plan. Under this operating plan, the station would function during Met games as it would on non-game days—the wider portion of the mezzanine, which is within the paid zone on most occasions but currently is converted to an unpaid zone during games would be kept as a part of the paid zone at all times. The unpaid corridor at the western end of the mezzanine would remain unpaid at all times and thus could serve as a means of crossing Roosevelt Avenue through the station. If this plan is implemented, NYCT would reposition the agent booth in the unpaid zone to provide added circulation space in the corridor.

- Subway trips were assigned to the Mets-Willets Point subway station. The assignments to specific stairways were based on logical patterns of travel to/from the subway station and Willets West and the District.
- Based on existing ridership patterns, bus trips were assigned to the study area bus routes as follows: 15 percent to the Q19, 70 percent to the Q66, and 15 percent to the Q48 bus routes. Assignments on these bus routes were made with logical origins and destinations. As with the analysis prepared for Phase 1A, the allocation of projected bus trips conservatively does not assume other potential service improvements, such as new bus routes or extension of existing bus routes.
- Walk-only trips, primarily within the District, were evenly distributed to the surrounding street network. As detailed above under “2018 With Action Condition,” a higher percentage of walk only trips in Phase 1B would be generated by other uses within the District, resulting in an increased internal trip capture percentage and a lower percentage of trips originating from Corona and Flushing. As a result of the increased internal capture percentage, a high number of walk-only trips generated by uses in the District would not appear on any of the pedestrian elements included for analysis. The walk-only trip assignments for Willets West during Phase 1B would be the same as those described for Phase 1A.

CHANGES IN THE PEDESTRIAN ENVIRONMENT

In addition to the geometric changes identified above under “2018 With Action Condition” and the completion of numerous internal roadways within the District to serve the future Phase 1B uses, Willets Point Boulevard would be realigned and change its intersection with 126th Street from its existing location at Roosevelt Avenue to a new location further north at approximately the same location as existing 38th Avenue. This change, along with the build-out of Phase 1B’s southern development components, would also necessitate the reconfiguration of the Roosevelt Avenue and 126th Street intersection’s northeast corner.

SUBWAY STATION OPERATIONS

Phase 1B project-generated subway trips were added to the 2028 No Action volumes in the same manner as described for Phase 1A. As shown in **Tables 14-131** and **14-132**, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels. Therefore, the proposed project would not result in any significant adverse subway station impacts under the 2028 With Action condition. However, as with the 2018 With Action condition, if NYCT decides to proceed with the reconfiguration of the Mets-Willets Point subway station, which

Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C =Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin= Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15- Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff= Friction Factor							

would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day management strategies. For purposes of disclosure in this Draft SEIS, any impacts that may be attributed to future passage of the reconfigured station may potentially be deemed unmitigatable.

SUBWAY LINE HAUL LEVELS

As described for the 2018 With Action condition, the projected peak hour subway trip increments were distributed to the peak load points on the No.7, the N, and the Q subway lines based on information provided by NYCT and ~~superimposed onto~~ added to the respective No Action line-haul volumes. As shown in **Table 14-133**, ~~with the overlay of these project-generated trips~~, the No. 7 subway line would continue to operate within guideline capacity during the AM peak period for the Manhattan-bound local service and during the PM peak period for the Flushing-bound service. As with the 2028 No Action condition, the Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2028 With Action condition. On average, the project-generated subway trips would add just ~~under over~~ five passengers per car to the Manhattan-bound express line at the peak load point during the AM peak period, which is ~~less~~ more than the *CEQR Technical Manual* impact threshold of five passengers per car. Hence, Phase 1B of the proposed project would ~~not~~ result in a significant adverse line-haul impact on the No. 7 line.

It should be noted that in the event NYCT is able to process one additional express train Manhattan-bound during the AM peak hour, as assumed in the DSEIS, the above significant adverse line-haul impact on the No. 7 line would not occur. Also as discussed, the City had consulted with the MTA on extending regular LIRR service to Willets Point when the actual demand shows that such service improvement is warranted. The addition of regular LIRR service to Willets Point would provide substantial relief to the No. 7 subway line and may prevent this significant adverse subway impact from materializing. Since there are constraints on what service improvements are available to NYCT, the identified significant line-haul capacity impact on the No. 7 line would likely remain unmitigated absent additional train service or the introduction of new LIRR service to the area.

~~In addition, because NYCT expects that there would be notable transfer activities between the No. 7 line and the N/Q lines at the Queensboro Plaza subway station (across the platform transfers), a detailed examination of line-haul conditions on the N/Q lines will be prepared, in coordination with NYCT, for the Final EIS. However, since the estimated Phase 1B project-generated increments would be fewer than 5 persons per subway car (up to 319 passengers in 120 to 130 train cars) on the N/Q trains, Phase 1B of the proposed project would similarly not result in a significant adverse line-haul impact on the N/Q lines.~~

Similar to the 2028 No Action condition, the N and the Q lines would continue to operate within guideline capacity during the PM peak hour and exceed the guideline capacity during the weekday AM peak period under the 2028 With Action condition. On average, the project-generated subway trips would add two passengers per car to each of the N and the Q lines at the peak load point during the AM peak period, which is fewer than the *CEQR Technical Manual* impact threshold of five passengers per car. Therefore, Phase 1B (2028) of the proposed project would not result in a significant adverse line-haul impact on the N and the Q lines.

Table 14-133

2028 With Action Condition: Peak Hour Subway Line Haul

Subway Lines Direction of Travel	Station	Trains/ Hour	Volume	Leave Load		Available Capacity
				Guideline Capacity	V/C Ratio	
AM Peak Period						
No. 7 Manhattan-bound Express	Woodside–61st Street	45 14	20,723 18,500	48,150 16,940	1.14 1.09	-2,573 -1,560

PM Peak Period						
No. 7 Flushing-bound Express + Local	Queensboro Plaza	23 25	23,977 23,529	27,830 30,250	0.86 0.78	3,853 6,721
N Queens-bound	Queensboro Plaza	7	8,029	10,150	0.79	2,121
Q (W) Queens-bound ¹	Queensboro Plaza	7	6,837	10,150	0.67	3,313
Sources: New York City Transit						
Notes:						
For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains.						
¹ W is a tentative designation for a line that would replace the Q service in Queens.						

BUS LINE HAUL LEVELS

As with the 2018 With Action condition analysis, no potential new or extended bus routes serving the project site were assumed in the 2028 (Phase 1B) bus line-haul analysis. Peak hour bus ridership levels were estimated by adding the incremental trips associated with the proposed project to bus stop locations along Roosevelt Avenue at 126th Street for the Q48 and to maximum load points along the Q19 and Q66. Impacts to bus line-haul levels would be considered significant if a proposed action would result in operating conditions above guideline capacities. As shown in **Table 14-134**, the eastbound and westbound Q48 would continue to operate within guideline capacity (54 passengers per bus) during the AM peak period but would operate above the guideline capacity during the PM peak period. The eastbound and westbound Q19 and Q66 would operate above guideline capacity during both the AM and PM peak periods. These projected increases in bus ridership beyond guideline capacities constitute significant adverse bus line-haul impacts.

Table 14-134

2028 With Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound	
			Load Point	AP		Load Point	AP
Q19	AM	3	Astoria Blvd/ 102nd St	(65)	3	Astoria Blvd/ 77th St	(61)
	PM	3	Astoria Blvd/ 94th St	(69)	3	Astoria Blvd/Humphrey St	(80)
Q48	AM	5	Roosevelt at 126th	47	3	Roosevelt at 126th	29
	PM	5	Roosevelt at 126th	(63)	5	Roosevelt at 126th	(79)
Q66 (to Woodside and LIC)	AM	15	Northern Blvd/ 110th St	(68)	14	Northern Blvd/ 72nd St	(64)
	PM	10	Northern Blvd/ 110th St	(78)	10	Northern Blvd/ 106th St	(87)
Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

Potential measures to mitigate the significant adverse bus line-haul impacts include scheduling additional buses to increase capacity. NYCT routinely monitors changes in bus ridership and would make the necessary service adjustments where warranted. These service adjustments are

subject to fiscal and operational constraints and, if implemented, are expected to occur over time. These measures are discussed in greater detail in Chapter 21, “Mitigation.”

STREET-LEVEL PEDESTRIAN OPERATIONS

The study area sidewalks, corner reservoirs, and crosswalks were assessed for the weekday AM, midday, PM, and pre-game peak periods, as well as, the weekend midday non-game, pre-game, and post-game peak periods by superimposing project-generated trips onto the No Action pedestrian analysis networks. The 2028 With Action peak hour pedestrian volumes are shown in **Appendix D**. As shown in **Tables 14-135** through **14-137**, all sidewalks and corner reservoirs would continue to operate at acceptable levels (within mid-LOS D, with a maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners) or incur degradations that, when compared to the No Action condition, do not exceed the *CEQR Technical Manual* sliding scale impact thresholds (See **Tables 14-81** and **14-82**). However, as shown in **Tables 14-138** and **14-139**, several study area crosswalks would operate beyond mid-LOS D (less than 19.5 SFP) and incur degradations that, when compared to the No Action condition, would exceed the *CEQR Technical Manual* sliding scale impact thresholds. These significant adverse pedestrian impacts are detailed below. Measures that can potentially mitigate these impacts are discussed in Chapter 21, “Mitigation.”

Northern Boulevard and 126th Street

- The east crosswalk would deteriorate to LOS F (4.9 SFP) from a No Action LOS A (5656.4 SFP), LOS F (4.8 SFP) from a No Action LOS A (5527.5 SFP), LOS F (6.5 SFP) from a No Action LOS A (584.6 SFP), LOS F (4.7 SFP) from a No Action LOS A (1681.7 SFP), LOS F (5.7 SFP) from a No Action LOS A (1086.8 SFP), and to LOS F (-2.7 SFP) from a No Action LOS A (130.4 SFP) during the weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

Roosevelt Avenue and 126th Street

- The west crosswalk would deteriorate to LOS F (-40.9 -22.6 SFP) from a No Action LOS A (152.5 SFP) and to LOS F (-34.7 -22.4 SFP) from a No Action LOS A (103.2 SFP) during the weekday pre-game and weekend pre-game peak periods, respectively.

34th Avenue and 126th Street

- The north crosswalk would deteriorate to beyond mid-LOS D (16.2 SFP) from a No Action LOS A (2139.3 SFP), and to LOS E (13.7 SFP) from a No Action LOS A (2704.6 SFP) during the weekday PM and weekend non-game peak periods, respectively.
- The south crosswalk would deteriorate to LOS E (9.9 SFP) from a No Action LOS A (5783.6 SFP), LOS E (14.7 SFP) from a No Action LOS A (3158.9 SFP), LOS E (8.4 SFP) from a No Action LOS A (1207.9 SFP), and to beyond mid-LOS D (19.1 SFP) from a No Action LOS D (21.9 SFP) during the weekday midday, weekday PM, weekend midday non-game, and weekend pre-game peak periods, respectively.
- The east crosswalk would deteriorate to beyond mid-LOS D (18.8 SFP) from a No Action LOS A (2035.8 SFP), LOS F (6.2 SFP) from a No Action LOS A (1502.7 SFP), LOS F (6.9 SFP) from a No Action LOS A (937.3 SFP), LOS F (3.8 SFP) from a No Action LOS A (78.0 SFP), LOS F (5.3 SFP) from a No Action LOS A (756.1 SFP), LOS F (4.2 SFP) from a No Action LOS A (9927.5 SFP), and to LOS F (5.1 SFP) from a No Action LOS A during the weekday AM, weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

	E Crosswalk	X	X	X	X	X	X	X
Notes: X = Significantly Impacted								

2032 WITH ACTION CONDITION

TRIP DISTRIBUTION AND ASSIGNMENT

Transit and pedestrian volumes for the 2032 With Action condition were estimated by overlaying peak hour volumes derived from the trip generation estimates presented in the “Traffic and Parking” section, onto the No Action analysis networks. These volumes were then assigned to the transit and pedestrian analysis locations based on the same assumptions described above for the 2028 With Action condition. In addition, the reasonable worst-case development scenario assumes that Lot B development would be completed by 2032, with its parking demand accommodated by available parking within the South Lot/Lot D. Therefore, the auto person trips associated with Lot B were assumed to cross Roosevelt Avenue at the Lot B driveway or 126th Street crosswalks to access the development.

CHANGES IN THE PEDESTRIAN ENVIRONMENT

In addition to the geometric changes described above for the 2018 and 2028 With Action conditions, the intersection of Roosevelt Avenue and Lot B driveway, which would incur more notable pedestrian trip-making, was added to the pedestrian study area. This intersection is comprised of three crosswalks, two crosswalks across Roosevelt Avenue and one crosswalk across the Lot B driveway along the north side of Roosevelt Avenue.

SUBWAY STATION OPERATIONS

Project-generated subway trips were added to the 2032 No Action volumes in the same manner as described for Phase 1A. As shown in **Tables 14-141** and **14-142**, all analyzed stairways and ramps and control areas would continue to operate at acceptable levels, except for the north stairway (S-3) on Roosevelt Avenue that faces Willets West, which would operate at LOS D with a v/c ratio of 1.21, 1.14, 1.20, and 1.02 during the weekday PM non-game, weekday pre-game, weekend pre-game, and weekend post-game peak periods, respectively, for the north stairway (S-2) on Roosevelt Avenue that faces the District, which would operate at LOS D with a v/c ratio of 1.1 during the weekday PM non-game peak period, and for the north stairway (M-4) that connects to the mezzanine and street level stairways, which would operate at LOS E with a v/c ratio of 1.34 during the weekday PM non-game peak period and LOS D with a v/c ratio of 1.10 and 1.08 during the weekday pre-game and weekend pre-game peak periods, respectively.

As described above, station stairway impacts are defined in terms of width increment threshold based on the minimum amount of additional capacity that would be required to either mitigate the location to its service conditions (LOS) under the No Action levels, or to bring it to a v/c ratio of 1.00, whichever is greater. Compared to the No Action service levels, the calculated WITs are greater than the *CEQR Technical Manual* WIT impact thresholds for stairway S-3 during the weekday PM non-game, weekday pre-game, and weekend pre-game peak periods, for stairway S-2 during the weekday PM non-game peak period, and for stairway M-4 during the weekday PM non-game, weekday pre-game, and weekend pre-game peak periods. Therefore, the proposed project would be expected to result in significant adverse subway station impacts under the 2032 With Action condition. Measures that can be implemented to mitigate these impacts are discussed in Chapter 21, “~~Mitigation~~.” In addition, as with the 2018 and 2028 With Action conditions, if NYCT decides to proceed with the reconfiguration of the Mets-Willets Point subway station, which would take place independent of the proposed project, additional interagency coordination is expected to take place to develop the appropriate game-day

Willets Point Development

management strategies. For purposes of disclosure in this Draft SEIS, any impacts that may be attributed to future passage of the reconfigured station may potentially be deemed unmitigatable.

Flushing-bound West Stair Turnstiles	6	726	364	0.80	0.90	0.45	B
Notes: Capacities were calculated based on rates presented in the <i>CEQR Technical Manual</i> (January 2012 edition). V/C = Vin / (Cin x Ff)+ Vx / (Cx x Sf x Ff) Vin = Peak 15 Min Entering Passenger Volume Cin = Total 15-Minute Capacity of all turnstiles for entering Passengers Vx = Peak 15-Minute Exiting Passenger Cx = Total 15-minute Capacity of all turnstile for exiting Passengers Sf = Surging Factor Ff= Friction Factor							

SUBWAY LINE HAUL LEVELS

As described for the 2018 With Action condition, the projected peak hour subway trip increments were distributed to the peak load points on the No.7, the N, and the Q subway lines based on information provided by NYCT and ~~superimposed onto~~ added to the respective No Action line-haul volumes. As shown in **Table 14-143**, ~~with the overlay of these project-generated trips~~, the No. 7 subway line would continue to operate within guideline capacity during the AM peak period for the Manhattan-bound local service and during the PM peak period for the Flushing-bound service. As with the 2032 No Action condition, the Manhattan-bound express service would continue to exceed the guideline capacity during the weekday AM peak period under the 2032 With Action condition. On average, the project-generated subway trips would add 11 passengers per car to the Manhattan-bound express line at the peak load point during the AM peak period, which is more than the *CEQR Technical Manual* impact threshold of five passengers per car. Hence, the proposed project in 2032 would be expected to result in a significant adverse line-haul impact on the No. 7 line. As discussed in the 2028 With Action condition above, the City had consulted with the MTA on extending regular LIRR service to Willets Point when the actual demand shows that such service improvement is warranted. The addition of regular LIRR service to Willets Point would provide substantial relief to the No. 7 subway line and may prevent this significant adverse subway impact from materializing. Since there are constraints on what service improvements are available to NYCT, the identified significant line-haul capacity impact on the No. 7 line would likely remain unmitigated absent the introduction of new LIRR service to the area.

Table 14-143
2032 With Action Condition: Peak Hour Subway Line Haul

Subway Lines Direction of Travel	Station	Trains/ Hour	Volume	Leave Load		Available Capacity
				Guideline Capacity	V/C Ratio	
AM Peak Period

		14	19,579	16,940	1.16	-2,639
<u>No.7</u> Manhattan-bound Local	40th Street	14	16,028	16,940	0.95	912
			14,169		0.84	2,771
<u>N</u> Manhattan-bound	<u>Queensboro Plaza</u>	8	13,730	11,600	1.18	-2,130
<u>Q (W)</u> Manhattan-bound ¹	<u>Queensboro Plaza</u>	8	13,003	11,600	1.12	-1,403
PM Peak Period						
<u>No.7</u> Flushing-bound Express + Local	Queensboro Plaza	23	25,247	27,830	0.91	2,583
		25	24,795	30,250	0.82	5,455
<u>N</u> Queens-bound	<u>Queensboro Plaza</u>	7	8,148	10,150	0.80	2,002
<u>Q (W)</u> Queens-bound ¹	<u>Queensboro Plaza</u>	7	6,956	10,150	0.69	3,194
Sources: New York City Transit						
Notes:						
For the AM peak hour, while a total of 29 trains would be expected to traverse the respective express and local peak load points, the total number of scheduled trains during this hour would be 28 trains.						
¹ W is a tentative designation for a line that would replace the Q service in Queens.						

In addition, because NYCT expects that there would be notable transfer activities between the No. 7 line and the N/Q lines at the Queensboro Plaza subway station (across the platform transfers), a detailed examination of line-haul conditions on the N/Q lines will be prepared, in coordination with NYCT, for the Final EIS. However, since the estimated Phase 2 project-generated increments would be fewer than 5 persons per subway car (up to 557 passengers in 120 to 130 train cars) on the N/Q trains, Phase 2 of the proposed project would not result in a significant adverse line-haul impact on the N/Q lines.

Similar to the 2032 No Action condition, the N and the Q lines would continue to operate within guideline capacity during the PM peak hour and exceed the guideline capacity during the weekday AM peak period under the 2032 With Action condition. On average, the project-generated subway trips would add three passengers per car to each of the N and the Q lines at the peak load point during the AM peak period, which is fewer than the *CEQR Technical Manual* impact threshold of five passengers per car. Therefore, Phase 2 (2032) of the proposed project would not result in a significant adverse line-haul impact on the N and the Q lines.

BUS LINE HAUL LEVELS

As with the 2018 and 2028 With Action condition analyses, no potential new or extended bus routes serving the project site were assumed in the 2032 bus line-haul analysis. Peak hour bus ridership levels were estimated by adding the incremental trips associated with the proposed project to bus stop locations along Roosevelt Avenue at 126th Street for the Q48 and to maximum load points along the Q19 and Q66. Impacts to bus line-haul levels would be considered significant if a proposed action would result in operating conditions above guideline capacities. As shown in **Table 14-144**, the eastbound and westbound Q48 would continue to operate within guideline capacity (54 passengers per bus) during the AM peak period but would operate above the guideline capacity during the PM peak period. The eastbound and westbound Q19 and Q66 would operate above guideline capacity during both the AM and PM peak periods. These projected increases in bus ridership beyond guideline capacities constitute significant adverse bus line-haul impacts.

Table 14-144

2032 With Action Condition: Bus Line Haul at NYCT Maximum and District Load Points

Route	Peak Period	Buses Per Hour	Eastbound		Buses Per Hour	Westbound	
			Load Point	AP		Load Point	AP
Q19	AM	3	Astoria Blvd/ 102nd St	(77)	3	Astoria Blvd/ 77th St	(74)
	PM	3	Astoria Blvd/ 94th St	(87)	3	Astoria Blvd/Humphrey St	(100)
Q48	AM	5	Roosevelt at 126th	54	3	Roosevelt at 126th	44
	PM	5	Roosevelt at 126th	(80)	5	Roosevelt at 126th	(103)
Q66 (to Woodside and LIC)	AM	15	Northern Blvd/ 110th St	(79)	14	Northern Blvd/ 72nd St	(77)
	PM	10	Northern Blvd/ 110th St	(103)	10	Northern Blvd/ 106th St	(114)
Note: AP = average passengers per bus; (#) = exceeds NYCT guideline capacity Source: Q48 ridership data provided by NYCT; Q19 and Q66 ridership data provided by the MTA Bus Company							

Potential measures to mitigate the significant adverse bus line-haul impacts include scheduling additional buses to increase capacity. NYCT routinely monitors changes in bus ridership and would make the necessary service adjustments where warranted. These service adjustments are subject to fiscal and operational constraints and, if implemented, are expected to occur over time. These measures are discussed in greater detail in Chapter 21, “~~Mitigation~~.”

STREET-LEVEL PEDESTRIAN OPERATIONS

The study area sidewalks, corner reservoirs, and crosswalks were assessed for the weekday AM, midday, PM, and pre-game peak periods, as well as, the weekend midday non-game, pre-game, and post-game peak periods by superimposing project-generated trips onto the No Action pedestrian analysis networks. The 2032 With Action peak hour pedestrian volumes are shown in **Appendix D**. As shown in **Tables 14-145** through **14-147**, all sidewalks and corner reservoirs would continue to operate at acceptable levels (within mid-LOS D, with a maximum of 8.5 PMF platoon flows for sidewalks; minimum of 19.5 SFP for corners) or incur degradations that, when

Willeys Point Development

compared to the No Action condition, do not exceed the *CEQR Technical Manual* sliding scale impact thresholds (See **Tables 14-81 and 14-82**). However, as shown in **Tables 14-148 and 14-149**, several study area crosswalks would operate beyond mid-LOS D (less than 19.5 SFP) and incur degradations that, when compared to the No Action condition, would exceed the *CEQR Technical Manual* sliding scale impact thresholds. These significant adverse pedestrian impacts are detailed below. Measures that can potentially mitigate these impacts are discussed in Chapter 21, “Mitigation.”

Notes: SFP = square feet per pedestrian.

N/A = Crosswalk volume is zero, and SFP is not calculable. LOS is assumed to be A.

+ Denotes a significant adverse impact.

Northern Boulevard and 126th Street

- The east crosswalk would deteriorate to LOS E (12.0 SFP) from a No Action LOS A (6403.9 SFP), LOS F (2.3 SFP) from a No Action LOS A (5642.1 SFP), LOS F (2.2 SFP) from a No Action LOS A (5513.2 SFP), LOS F (3.5 SFP) from a No Action LOS A (583.0 SFP), LOS F (2.5 SFP) from a No Action LOS A (1672.8 SFP), LOS F (3.2 SFP) from a No Action LOS A (1083.9 SFP), and to LOS F (-2.9 SFP) from a No Action LOS A (129.6 SFP) during the weekday AM, weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

Roosevelt Avenue and 126th Street

- The west crosswalk would deteriorate to LOS F ~~E~~ (6.7 ~~8.0~~ SFP) from a No Action LOS A (1560.4 SFP), LOS F (2.6 ~~4.4~~ SFP) from a No Action LOS A (2031.8 SFP), LOS F (-7.4 ~~-4.8~~ SFP) from a No Action LOS A (149.4 SFP), LOS F (4.3 ~~5.7~~ SFP) from a No Action LOS A (1072.1 SFP), LOS F (-5.4 ~~-4.0~~ SFP) from a No Action LOS A (99.5 SFP), and to

LOS ~~E~~ E (7.8 ~~9.6~~ SFP) from a No Action LOS A (183.4 SFP) during the weekday midday, weekday PM, weekday pre-game, weekend non-game, weekend pre-game, and weekend post-game peak periods, respectively.

The north crosswalk would deteriorate to beyond mid-LOS D (16.3 ~~16.4~~ SFP) from a No Action LOS A (2680.2 SFP), and to beyond mid-LOS D (17.3 ~~17.4~~ SFP) from a No Action LOS A (537.3 SFP) during the weekday PM and weekend post-game peak periods, respectively.

34th Avenue and 126th Street

- The north crosswalk would deteriorate to beyond mid-LOS D (16.8 SFP) from a No Action LOS A, LOS E (9.7 SFP) from a No Action LOS A (2131.7 SFP), and to LOS F (8.0 SFP) from a No Action LOS A (2699.8 SFP) during the weekday midday, weekday PM, and weekend midday non-game peak periods, respectively.
- The south crosswalk would deteriorate to LOS E (13.9 SFP) from a No Action LOS A (2947.4 SFP), LOS F (1.9 SFP) from a No Action LOS A (5767.3 SFP), LOS F (6.8 SFP) from a No Action LOS A (3150.8 SFP), and to LOS F (3.4 SFP) from a No Action LOS A (1204.7 SFP) during the weekday AM, weekday midday, weekday PM, and weekend midday non-game peak periods, respectively.
- The east crosswalk would deteriorate to LOS E (10.6 SFP) from a No Action LOS A (2035.8 SFP), LOS F (4.6 SFP) from a No Action LOS A (1394.7 SFP), LOS F (4.8 SFP) from a No Action LOS A (937.3 SFP), LOS F (3.0 SFP) from a No Action LOS A (76.9 SFP), LOS F (3.7 SFP) from a No Action LOS A (755.4 SFP), LOS F (3.3 SFP) from a No Action LOS A (9908.5 SFP), and to LOS F (5.4 SFP) from a No Action LOS A during the weekday AM, weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

Roosevelt Avenue and the Lot B Driveway

- The north crosswalk would operate at LOS E (14.8 ~~13.7~~ SFP), LOS E (13.3 ~~11.8~~ SFP), LOS F (7.9 ~~7.3~~ SFP), LOS ~~D~~ E (15.3 ~~14.3~~ SFP), LOS E (11.7 ~~10.7~~ SFP), LOS ~~D~~ E (15.5 ~~14.2~~ SFP), and LOS D (17.7 ~~16.1~~ SFP) during the weekday AM, weekday midday, weekday PM, weekday pre-game, weekend midday non-game, weekend pre-game, and weekend post-game peak periods, respectively.

~~126th Street and New Willets Point Boulevard~~

- ~~• The south crosswalk would operate at beyond mid-LOS D (18.7 SFP) during the weekday PM peak period.~~

The significant adverse transit and pedestrian impacts detailed above for the 2032 analysis year are summarized in **Table 14-150**.

Table 14-150

Summary of 2032 Significant Adverse Transit and Pedestrian Impacts

Analysis Element		Analysis Time Period						
		Weekday				Weekend		
		AM	Midday	PM	Pre-Game	Midday	Pre-Game	Post-Game
Subway Impacts

Roosevelt Ave & Lot B Driveway	N Crosswalk	X	X	X	X	X	X	X
Notes:		X = Significantly Impacted						

L. VEHICULAR AND PEDESTRIAN SAFETY

Crash data for the study area intersections were obtained from the New York State Department of Transportation (NYSDOT) for the time period between January 1, 2009 and December 31, 2011. The data obtained quantify the total number of reportable accidents (involving fatality, injury, or more than \$1,000 in property damage), fatalities, and injuries during the study period, as well as a yearly breakdown of pedestrian- and bicycle-related accidents at each location. According to the *CEQR Technical Manual*, a high accident location is one where there were five or more pedestrian/bicyclist-related accidents or 48 or more reportable and non-reportable accidents in any consecutive 12 months within the most recent 3-year period for which data are available.

During the January 1, 2009 to December 31, 2011 3-year period, a total of 709 reportable and non-reportable accidents, 2 fatalities, 697 injuries, and 166 pedestrian/bicyclist-related accidents occurred at the study area intersections. A rolling total of accident data identifies seven study area intersections as high pedestrian accident locations in the 2009 to 2011 period. These locations are 114th Street at Roosevelt Avenue, Main Street at Northern Boulevard, Main Street at Roosevelt Avenue, Main Street at 41st Avenue/Kissena Boulevard, Union Street at Northern Boulevard, Union Street at Roosevelt Avenue and Parsons Boulevard at Northern Boulevard. **Table 14-151** depicts total accident characteristics by intersection during the study period, as well as a breakdown of pedestrian and bicycle accidents by year and location. **Table 14-152** shows a detailed description of each accident at the seven high accident locations during the three year period.

Table 14-151
Accident Summary

Intersection		Study Period					Accidents by Year

114TH STREET AND ROOSEVELT AVENUE

Based on the review of the accident history at the intersection of 114th Street and Roosevelt Avenue, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of 114th Street and Roosevelt Avenue is signalized and provides two high-visibility crosswalks and two regular crosswalks. In terms of project-generated activity, the intersection would experience incremental peak-hour volume increases of approximately 810 or fewer vehicle trips and 200 or fewer pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, “~~Mitigation~~,” the predicted impacts at this intersection could be fully mitigated with standard traffic engineering measures under the 2018 and 2028 With Action conditions. For the 2032 With Action condition, the predicted impacts at this intersection would be fully mitigated during the non-game analysis peak hours and would be partially mitigated during the game day analysis peak hours. In addition, the Queens Development Group, LLC (QDG), in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in this SEIS or similar measures identified through the traffic monitoring plan.

Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches), the installation of countdown timers for all crosswalks, and restriping the north and south crosswalks as high-visibility crosswalks, can be implemented to improve pedestrian safety at this intersection.

MAIN STREET AND NORTHERN BOULEVARD

Based on the review of the accident history at the intersection of Main Street and Northern Boulevard, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, Main Street and Northern Boulevard is a signalized, three-way intersection with three high-visibility crosswalks. In addition, countdown timers are installed for all crosswalks at this intersection. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 580 or fewer vehicle trips (all through) and there would not be any project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could not be mitigated with standard traffic engineering measures under the 2032 With Action condition. However, as described above, all the proposed project-generated vehicle trips would be through trips at this intersection and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection, while a review of the vehicle and pedestrian accident details presented in **Table 14-152** indicates that the majority of pedestrian-related accidents were caused by pedestrian inattentiveness and driver failure to yield right of way. Since these accidents occurred primarily during vehicles making left and right turning movements, the through vehicle trips generated by the proposed project is not anticipated to result in additional conflicts with normal pedestrian flow. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches and “Wait for Walk Signal” signs for pedestrians) can be implemented to improve pedestrian safety at this intersection.

MAIN STREET AND ROOSEVELT AVENUE

Based on the review of the accident history at the intersection of Main Street and Roosevelt Avenue, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of Main Street and Roosevelt Avenue is signalized and provides four school crosswalks. In addition, countdown timers are installed at all crosswalks at this intersection. Based on the detailed description, half of the pedestrian-related accidents were related to pedestrian error, with pedestrians crossing against the signal listed as a

contributing factor in six of the twenty-two accidents. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 220 or fewer vehicle trips (all through) and there would not be any project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could be fully or partially mitigated with standard traffic engineering measures during the weekday AM and weekend midday non-game, weekday and weekend pre-game and weekend post-game peak hours, and could not be mitigated during the weekday midday and PM non-game peak hours under the 2032 With Action condition. However, as described above, all the proposed project-generated vehicle trips would be through trips at this intersection and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection, while a review of the vehicle and pedestrian accident details presented in **Table 14-152** indicates that the majority of pedestrian-related accidents were caused by pedestrian inattentiveness and driver failure to yield right of way. Since these accidents occurred primarily during vehicles making left and right turning movements and pedestrian inattentiveness, the through vehicle trips generated by the proposed project is not anticipated to result in additional conflicts with normal pedestrian flow. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches and “Wait for Walk Signal” signs for pedestrians) can be implemented to improve pedestrian safety at this intersection.

MAIN STREET AND 41ST AVENUE/KISSENA BOULEVARD

Based on the review of the accident history at the intersection of Main Street and 41st Avenue/Kissena Boulevard, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of Main Street and 41st Avenue/Kissena Boulevard is signalized and provides four school crosswalks. In addition, countdown timers are installed at the Kissena Boulevard and Main Street crosswalks. Based on the detailed description, half of the pedestrian-related accidents were related to vehicles making left or right turning movements. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 10 or fewer vehicle trips and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during the weekday and weekend non-game midday peak hours and the weekend pre-game peak hour under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could be fully mitigated with standard traffic engineering measures under the 2032 With Action condition. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches), the installation of countdown timers on the remaining two crosswalks (the east and west crosswalks of 41st Avenue), and restriping a faded crosswalk on the western leg of 41st Avenue, can be implemented to improve pedestrian safety at this intersection.

UNION STREET AND NORTHERN BOULEVARD

Based on the review of the accident history at the intersection of Union Street and Northern Boulevard, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of Union Street and Northern Boulevard is signalized and provides three school crosswalks and one regular crosswalk. In addition, countdown timers are installed at all crosswalks at this intersection and School Advance Warning Signs are located at all approaches except to the west. Based on the detailed description, two-thirds of the pedestrian-related accidents were related to vehicles making left or right turning movements. In all of these accidents, pedestrians were crossing with the signal; failure to yield right-of-way was listed as a contributing factor in five. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 580 or fewer vehicle trips (mostly through) and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could be partially mitigated with standard traffic engineering measures during all analysis peak hours except for the weekday AM non-game peak hour where it could not be mitigated under the 2032 With Action condition. However, as described above, most of the proposed project-generated vehicle trips would be through trips at this intersection and there would not be any project-generated pedestrian trips at any crosswalks at this intersection, while a review of the vehicle and pedestrian accident details presented in **Table 14-152** indicates that the majority of pedestrian-related accidents were caused by pedestrian inattentiveness and driver failure to yield right of way. Since these accidents occurred primarily during vehicles making left and right turning movements, the mostly through vehicle trips generated by the proposed project is not anticipated to result in additional conflicts with normal pedestrian flow. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents.

Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches) and restriping the southern crosswalk as a high-visibility crosswalk, can be implemented to improve pedestrian safety at this intersection.

UNION STREET AND ROOSEVELT AVENUE

Based on the review of the accident history at the intersection of Union Street and Roosevelt Avenue, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of Union Street and Roosevelt Avenue is signalized and provides two school crosswalks and two regular crosswalks. Based on the detailed description, half of the pedestrian-related accidents were related to vehicles making left or right turning movements. In all of these accidents, pedestrians were crossing with the signal. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 220 or fewer vehicle trips (mostly through) and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could not be mitigated with standard traffic engineering measures under the 2032 With Action condition. However, as described above, most of the proposed project-generated vehicle trips would be through trips at this intersection and there would not be any project-generated pedestrian trips at any crosswalks at this intersection, while a review of the vehicle and pedestrian accident details presented in **Table 14-152** indicates that the majority of pedestrian-related accidents were caused by driver failure to yield right of way. Since these accidents occurred primarily during vehicles making left and right turning movements, the mostly through vehicle trips generated by the proposed project is not anticipated to result in additional conflicts with normal pedestrian flow. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches), the installation of countdown timers on all crosswalks, and restriping the north and south crosswalks as high-visibility crosswalks, can be implemented to improve pedestrian safety at this intersection.

PARSONS BOULEVARD AND NORTHERN BOULEVARD

Based on the review of the accident history at the intersection of Parsons Boulevard and Northern Boulevard, no prevailing trends with regard to geometric deficiencies were identified as the primary causes of recorded accidents. With respect to geometric deficiencies that could potentially cause safety hazards, the intersection of Parsons Boulevard and Northern Boulevard is signalized and provides four high-visibility crosswalks. In addition, countdown timers are installed at the north and south crosswalks at this intersection. Based on the detailed description,

half of the pedestrian-related accidents were related to vehicles making left or right turning movements. In terms of project-generated activity, this intersection is located in the secondary traffic study area and would experience incremental peak-hour volume increases of approximately 580 or fewer vehicle trips (mostly through) and there would be a negligible number of project-generated pedestrian trips at any crosswalks at this intersection during each of the seven analysis peak hours by the 2032 With Action condition. As discussed in the “Traffic and Parking” section, this intersection would be impacted during all seven analysis peak hours under the 2032 With Action condition.

As described in Chapter 21, ~~“Mitigation,”~~ the predicted impacts at this intersection could be fully or partially mitigated with standard traffic engineering measures during all analysis peak hours under the 2032 With Action condition. However, as described above, most of the proposed project-generated vehicle trips would be through trips at this intersection and there would not be any project-generated pedestrian trips at any crosswalks at this intersection, while a review of the vehicle and pedestrian accident details presented in **Table 14-152** indicates that the majority of pedestrian-related accidents were caused by pedestrian inattentiveness and driver failure to yield right of way. Since these accidents occurred primarily during vehicles making left and right turning movements, the mostly through vehicle trips generated by the proposed project is not anticipated to result in additional conflicts with normal pedestrian flow. In addition, QDG, in consultation with the lead agency and NYCDOT, would develop and conduct a detailed traffic monitoring plan at various interim buildout phases of the proposed project to determine whether actual future With Action conditions have, in fact, resulted in significant traffic impacts and verify the need and effectiveness of the proposed mitigation measures identified in the this SEIS or similar measures identified through the traffic monitoring plan. Therefore, the proposed project is not anticipated to exacerbate any of the current causes of pedestrian-related accidents. Nonetheless, additional safety measures, such as the installation of pedestrian safety signs (i.e., “Turning Vehicles Yield to Pedestrians” signs on all approaches), the installation of countdown timers on the remaining two crosswalks, can be implemented to improve pedestrian safety at this intersection.

M. DUAL EVENT CONDITIONS WITH U.S. TENNIS OPEN

Met home games and the US Tennis Open event occur during the same two-week period in late August/early September every other year. The 2008 FGEIS stated that the proposed Willets Point Development Plan “would add significant traffic volumes to the surrounding highway network and key local roadways, such as Northern Boulevard and Roosevelt Avenue,” and that the Dual Event Condition with a Met game and the US Open “would experience worsened delays and additional queuing compared with the No Action condition,” and that “more rigorous management of traffic operations at locations where control is already maintained during the Dual Event Condition would likely be necessary with the proposed Development Plan,” but that “this condition would represent an infrequent special case with the overlap of two concurrent events in combination with the expected traffic activity of the proposed Development Plan”. These conclusions vis-à-vis the US Open would again apply to conditions with the newly-proposed Development Plan that is the subject of this SEIS.

N. POTENTIAL MAJOR LEAGUE SOCCER STADIUM

TRAFFIC AND PARKING

Major League Soccer (MLS) is considering a number of existing venues or potential future development sites in the City to house its newly-created New York team. Major League Soccer

(MLS) is proposing to build a stadium. One of these sites is within the eastern section of Flushing Meadows-Corona Park on Industry Pond. While there has been no definitive decision as to where a new stadium might be sited, this Final SEIS continues to consider a stadium on Industry Pond in Flushing Meadows-Corona Park as a possible site and continues to make reasonable assumptions as to the playing schedule and impacts that such a project may generate, as was discussed in the Draft SEIS.

The stadium plans currently call for an initial 25,000-seat stadium that can be expanded to accommodate 10,000 more seats—to a total of 35,000 seats—in the future. The planned year would be 2016, with the expectation that the stadium would be expanded approximately ten years later, in or about 2026. It is possible that the full stadium shell could be built by 2016 with the initial 25,000 seats ready for use at that time, with the additional seating added ten years or so later. MLS games are expected to occur on approximately 17 to 20 days of the year (17 pre-season and regular season games, plus up to three playoff games should the team advance to and through the playoffs). Scheduling of Met and soccer games would avoid any concurrency or overlap in trips between games at the two stadiums. Similarly, off-season events that may take place at CitiField and the MLS stadium would be coordinated to avoid any concurrency or overlap in scheduling. Since a Met game and an MLS game would be representative worst-case events at the respective venues, these other off-season events are expected to generate relatively smaller attendances and trip-making. Thus, the discussion below focuses on a comparison of trip-making characteristics between a Met game and an MLS game.

The expectation is that the vast majority of MLS games (approximately 85 percent) would be played on a Saturday night and the remainder would be played on a weekday night (15 percent). MLS parking would occur primarily within parking facilities used by Met fans and would be supplemented by parking spaces to be provided within the park, likely under a section of the Van Wyck Expressway or other parking lots within Flushing Meadows-Corona Park. While the exact location and number of parking spaces to be provided within the park is not known at this time, the most recent information from MLS on the anticipated parking within the park and its planned use of Mets parking was used in the assessments discussed below.

Because MLS is expecting to start with a stadium with 25,000 seats and expand to one with 35,000 seats—both less than the capacity of CitiField—it is not expected that an MLS game would add more traffic to the roadway network than would a Met game. Traffic analyses being prepared for MLS by others indicate that the attendance would be approximately 90 percent of stadium capacity (22,500 fans for a 25,000 seat stadium; 31,500 fans for a 35,000 seat stadium) on a typical day, which would be within the 85th percentile attendance analyzed for conditions with a Met game. For the purposes of a conservative analysis, the assessments presented below are based on the construction of 35,000 seats in 2016. The auto and taxi share of MLS trips (estimated by MLS based on actual surveys of MLS games to range between 49 and 52 percent) is also expected to be lower than those for Met trips (62 percent per the Shea Stadium Redevelopment FEIS, 2001). For the average number of patrons per vehicle, MLS estimated that it would be the same as the Mets, at 2.7. MLS also estimated based on surveys that 55 percent of the arrivals on weekends and 65 percent of the arrivals on weekdays would occur during the peak arrival hour, as compared to 61 percent for the Met. So overall, an MLS event would generate fewer vehicle trips than would a Met game. Although traffic routes used by MLS fans will be similar to those used by Met fans, it is possible that MLS vehicular trip patterns will be slightly different from those for Met games since trip origins may be somewhat different and since some percentage of MLS fans will take routes to parking within Flushing Meadows-Corona Park that are not used by Met fans.

Although consideration of an MLS event would include less overall vehicular traffic than would a Met game, two sets of traffic assignments were conducted—one for just Met game-generated vehicle trips and the other for just MLS soccer-generated vehicle trips for both types of events for a weeknight arrival peak hour and for a weekend arrival peak hour. This was done so this SEIS could preliminarily identify which, if any, traffic analysis locations could possibly have more vehicle traffic in the baseline (No Action) condition due to differences in traffic routes used to get to each venue, especially since MLS fans driving to a soccer game would, to some degree, park at locations within Flushing Meadows-Corona Park and therefore use routes that Met fans might not use en route to parking at CitiField. These sets of traffic assignments—and the conclusions reached—are preliminary, for the purposes of this SEIS, since they are based on preliminary information available at this time. ~~Follow-up analyses will be conducted if updated information becomes available, potentially during the period between certification of this Draft SEIS and the Final SEIS. There has been no new information since certification of the Draft SEIS; therefore the assessments presented below are based on the information cited above.~~ Based on the assessments presented below, for the majority of the traffic study area intersections, an MLS game would result in fewer vehicle trips than a Met game. However, based on the assessment of information available at this time, it is possible that higher traffic volumes could occur at up to nine study area intersections with an MLS game during peak arrival periods. These intersections could potentially incur worsened significant impacts with an MLS game in the background condition, or it is also possible that the magnitude of significant impacts identified earlier in this chapter would remain the same or could be lower with an MLS game. For those intersections that could operate at somewhat worsened conditions with an MLS event in the background instead of a Met game, it is possible that additional mitigation may be needed or it may be possible that one or more additional intersections could not be mitigated.

WEEKNIGHT PRE-GAME VEHICLE TRAFFIC ARRIVALS

Traffic assignments were prepared for the peak arrival hour for a weeknight Met game and for the peak arrival hour for a weeknight MLS game, and a comparison was made of traffic volumes for each traffic analysis location (intersection analysis locations and highway segments). The Met weeknight pregame traffic arrival peak hour (for a 7 PM start time) is 5:30 to 6:30 PM; the MLS weeknight pregame traffic arrival peak hour (for a 7 PM expected start time) is expected to be somewhat later at 6:15 to 7:15 PM. Overall, Met game vehicle trips are approximately 43 percent higher than MLS vehicle trips. Also, MLS games are only expected to occur on weeknights approximately three times per year. The detailed route-by-route, intersection-by-intersection trip assignments, however, show—in Phase 1A with a fully built 35,000 seat MLS stadium—that there could be up to nine intersections where background volumes for an MLS event are higher than those for a Met game, including the following:

- Northern Boulevard at Parsons Boulevard, Union Street, Main Street, and Prince Street
- Northern Boulevard westbound service road at College Point Boulevard
- Northern Boulevard at 126th Street
- College Point Boulevard at Roosevelt Avenue and at Sanford Avenue
- Roosevelt Avenue at 126th Street

There are three other intersections analyzed along Roosevelt Avenue west of CitiField—at 114th Street, 111th Street, and 108th Street—where the increase in traffic volumes with MLS is just one vehicle trip higher than for Met game nights; it is unlikely that this difference of just one vehicle trip would significantly change level of service, delay or significant traffic impact

conclusions at these three intersections, where such an increase would represent less than 0.1 percent of the existing peak hour traffic volumes at these intersections. At some of the nine intersections cited above, the increase of vehicle trips between Met games and MLS games may occur for one specific traffic movement (e.g., left turns from westbound Roosevelt Avenue onto southbound College Point Boulevard) while the overall volumes through the intersection are higher for Met games than for MLS games. Therefore, the number of intersections with worsened conditions may be fewer than the nine intersections listed above.

As noted above, the preliminary volume comparison is based on the full 35,000 seat MLS stadium being built in 2016 (and is assumed to thus be in place by the proposed project's Phase 1A Build year) even though future MLS updates may confirm that only a 25,000 seat stadium would be in place by Phase 1A, in which case the magnitude of MLS-generated volumes would be lower and its volumes may exceed Met-generated volumes at fewer than the nine intersections listed above. For Phases 1B and 2, with the full 35,000 seat MLS stadium built, the comparison of vehicle trip assignments shows that the same nine intersections cited above could have volumes higher than on Met weeknight games.

Overall, MLS trips that are expected to arrive via the highway network are lower than Met trips arriving from the same origins via the highway network. However, due to the proposed MLS parking facilities located under a section of the Van Wyck Expressway or other parking lots within Flushing Meadows-Corona Park, three highway mainline segments and ramps analyzed for this SEIS would experience volumes higher than for a Met game: the southbound Van Wyck Expressway between Roosevelt Avenue and the LIE; the ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway; and the ramp from the southbound Whitestone Expressway to the southbound Van Wyck Expressway. These three highway elements do not carry any Met trips under existing conditions and are not expected to carry any Met trips under No Action or With Action conditions.

WEEKNIGHT POST-GAME VEHICLE TRAFFIC DEPARTURES

The weeknight post-game condition would generally occur much later at night, and only three times per year, when traffic generated by the proposed project would be much lower and background traffic volumes are much lower than in the peak hours analyzed in the FGEIS and in the SEIS. Therefore a weeknight post-game traffic analysis is not needed either for background conditions with an MLS game or with a Met game. As noted above, an MLS game would only occur approximately three times per year on a weeknight.

WEEKEND PRE-GAME VEHICLE TRAFFIC ARRIVALS

Traffic assignments were also prepared for the peak arrival hour for a weekend Met game and for the peak arrival hour for a weekend MLS game, and a comparison was made of traffic volumes for each traffic analysis location (intersection analysis locations and highway segments). Overall, Met game vehicle trips are approximately 47 percent higher than MLS vehicle trips. The detailed route-by-route, intersection-by-intersection trip assignments, however, show—in Phase 1A with a fully built 35,000 seat MLS stadium -- that there could be up to nine intersections where background volumes for an MLS event are higher than those for a Met game; these are the same locations listed above for weeknights.

As noted above for the weeknight pre-game condition, at some of the intersections, the increase of vehicle trips between Met games and MLS games may occur for one specific traffic movement (e.g., left turns from westbound Roosevelt Avenue onto southbound College Point Boulevard) while the overall volumes through the intersection are higher for Met games than for

MLS games. Therefore, the number of intersections with worsened conditions may be less than the nine intersections listed above.

Overall, MLS trips that are expected to arrive via the highway network are lower than Met trips arriving from the same origins via the highway network. However, due to the proposed MLS parking facilities located under a section of the Van Wyck Expressway or other parking lots within Flushing Meadows-Corona Park, three highway mainline segments and ramps analyzed for this SEIS would experience volumes higher than for a Met game: the southbound Van Wyck Expressway between Roosevelt Avenue and the LIE; the ramp from the northbound Whitestone Expressway to the southbound Van Wyck Expressway; and the ramp from the southbound Whitestone Expressway to the southbound Van Wyck Expressway. These three highway elements do not carry any Met trips under existing conditions and are not expected to carry any Met trips under No Action or With Action conditions.

WEEKEND POST-GAME VEHICLE TRAFFIC DEPARTURES

The weekend post-game condition would generally occur much later at night as was noted above for weeknight post-game conditions, when traffic generated by the proposed project would be much lower and background traffic conditions are also much lower than in the peak hours analyzed in the FGEIS and in the SEIS. Therefore a weekend post-game traffic analysis is not needed either for background conditions with an MLS game or with a Met game.

LEVELS OF SERVICE AND THE POTENTIAL FOR ADDITIONAL OR WORSENERD SIGNIFICANT TRAFFIC IMPACTS

For conditions with a Met game, previous sections of this chapter indicate that eight of the nine intersections identified above would be significantly impacted in Phases 1A and 1B of the proposed project; during Phase 2 of the proposed project, all nine would be significantly impacted on Met game nights. These intersections could potentially incur worsened significant impacts with an MLS game in the background condition, or it is also possible that the magnitude of significant impacts identified earlier in this chapter would remain the same or could be lower with an MLS game. As described in Chapter 21, “Mitigation”, several of these intersections can be mitigated using standard traffic capacity improvements such as signal timing changes, parking regulation modifications, lane re-striping, geometric improvements, or other measures for conditions with a Met game as part of the background condition. For those intersections that could operate at somewhat worsened conditions with an MLS event in the background instead of a Met game, it is possible that additional mitigation may be needed or it may be possible that one or more additional intersections could not be mitigated. An updated analysis of these intersections ~~is not needed since new will be conducted if updated~~ MLS information ~~has not become available~~ becomes available, potentially during the period between ~~since~~ certification of this ~~the~~ Draft SEIS, and the Final SEIS. If more information is available, ~~Therefore,~~ the traffic assignments conducted for this ~~the~~ Draft SEIS ~~will be reviewed and do not need to be~~ updated, if necessary, and a full level of service impact analysis ~~is not needed~~ will be conducted for locations where volumes with MLS would significantly exceed those with a Met game, on weekends, to determine whether new impacts or worsened impacts could be expected under future baseline conditions with an MLS stadium. A weeknight pregame traffic level of service analysis ~~would~~ is not be needed since it is expected that MLS will have games on only three weeknights of the year.

TRANSIT AND PEDESTRIANS

For transit use, the current projections prepared for MLS show approximately 45 percent higher peak hour usage of the Mets-Willets Point subway station for weekday and weekend arrival than accounted for Met games in this ~~Draft~~ Final SEIS's transit analysis. At the station's street-level stairways on the north side of Roosevelt Avenue, although significant adverse impacts have been identified, they would not be exacerbated by an MLS event since all of its trip-making through this station would be directed to the south end of the station. The MLS pedestrian movements would be facilitated by the station's southern connection to the passerelle, similar to what would occur during the US Open at the National Tennis Center. However, there would be more projected subway riders at the station elements connecting to the No. 7 train platforms (i.e., stairways, ramps, and control areas) during the peak arrival hour to an MLS game than to a Met game. Based on the impact analysis conducted for these station elements, no significant adverse impacts were identified with Met trips assumed in the future No Action background. It is expected that the higher MLS trips would not result in new impacts on the Manhattan-bound ramps and turnstiles during these peak arrival periods. However, at the Queens-bound stairways and connecting turnstiles, the higher background volumes from the MLS could result in the potential for new significant adverse impacts that would not otherwise occur with the Mets. Since there has not been new ~~Between the Draft and Final SEIS, if more updated information made available on from the MLS study becomes available, it will be used to examine~~ certification of the Draft SEIS and preparation of this Final SEIS, no additional analyses were prepared to ascertain the potential for significant adverse impacts at these station elements or, if necessary, develop. If impacts are identified, improvement measures, such as stairway widenings, will be explored to mitigate these impacts to the extent practicable. Therefore, should the impacts occur, they would be deemed unmitigatable for the purposes of this Final SEIS. If no feasible measures can be identified at that time, these impacts will be disclosed as unmitigatable. In addition, as discussed in Section ~~I H~~, "Scope of Analysis (Transit and Pedestrians)," NYCT's potential future reconfiguration of the Mets-Willets Point subway station to maintain a single set of fare zone condition for game-day and non-game day operations could alter the circulation path of MLS patrons through the station, possibly via more constrained station elements. This potentially more congested background condition overlaid with project-generated trips could result in worse or new significant adverse impacts at the existing and future station elements. Accordingly, potential improvement measures will be explored to mitigate these impacts to the extent practicable. If no feasible measures can be identified at that time, these impacts will likewise be disclosed as unmitigatable. However, no changes to operating plans were announced by NYCT between the Draft and Final Supplemental Environmental Impact Statements; therefore, any potential changes that may be considered for future implementation will be addressed outside of this environmental review.

With regard to pedestrian conditions analyzed in this ~~Draft~~ Final SEIS, an MLS game may also result in increased volumes at some of the study area pedestrian analysis locations. As discussed above, all MLS trips made to the Mets-Willets Point subway station would be directed onto the passerelle and would not affect on-street elements in the pedestrian study area. MLS's projected higher travel by City buses would also have minimal effects (Q48 passengers only along Roosevelt Avenue) since this would still be a very small percentage of MLS's overall trip-making. Its walk-only trips would largely be limited to locations near the MLS stadium, outside of this ~~Draft~~ Final SEIS's pedestrian study area. The only travel that could potentially have an effect on the study area pedestrian elements would be related to auto trips accommodated in Met parking facilities and walking via the passerelle to the MLS stadium. For those parking in

Southfield/Lot D, they would not traverse the study area pedestrian elements. Hence, during Phase 1B and Phase 2 of the proposed project, with all MLS parkers accommodated within parking near the MLS stadium and within parking in Southfield/Lot D, a background condition with a Met game would be conservatively representative for evaluating potential impacts at this ~~Draft~~ Final SEIS's pedestrian study area.

During Phase 1A when approximately 2,750 parking spaces would be provided in the interim parking lots within the District, Met and MLS parkers would need to walk at-grade for part of their trips to CitiField or the MLS stadium. The numbers of vehicles arriving at the District's interim parking lots during the Met weekday pre-game and weekend pre-game peak hours were estimated at approximately 1,500. Based on MLS's current projections, the corresponding numbers of MLS parkers during these arrival periods would be approximately 1,750. At 2.7 persons per vehicle, the Met arrivals during the weekday pre-game and weekend pre-game peak hours would yield approximately 4,000 pedestrians, who would need to cross 126th Street to get to CitiField. The corresponding numbers of MLS pedestrians during these arrival periods, also at 2.7 persons per vehicle, would be approximately 4,700. On Met game days, traffic control officers are present to facilitate vehicular and pedestrian flow and to minimize conflicts at strategic locations. For those parking at the District's interim parking lots during Phase 1A, pedestrians crossing 126th Street between 34th and Roosevelt Avenues are expected to be managed by these traffic control officers. Game-day management of patrons parking at the District's interim parking lots is expected to be comparable on an MLS game day. After crossing over to the west side of 126th Street, however, the MLS patrons would be expected to either use the pedestrian plaza adjacent to CitiField and Willets West or along the north side of Roosevelt Avenue to walk to the grand stairs connecting to the Mets-Willets Point subway station. As with Met game days, crossing Roosevelt Avenue at this location is restricted by traffic control officers. Therefore, these MLS patrons would be expected then to walk up the grand stairs, through the station, and continue south onto the passerelle, or as noted above via other existing or new station circulation elements.

As discussed above, crossing 126th Street between 34th and Roosevelt Avenues would be managed by traffic control officers and the slightly higher pedestrian volumes associated with the MLS parkers would not be expected to materially affect how the game-day management here would take place. However, at Roosevelt Avenue, an MLS game could result in more pedestrian trips at the 126th Street north crosswalk and on the north sidewalk of Roosevelt Avenue between 126th Street and the Mets-Willets Point subway station. Under Phase 1A, neither of these pedestrian elements was determined to incur significant adverse pedestrian impacts. ~~If~~ Since there has not been new information on the MLS project ~~becomes available between~~ since certification of the Draft and Final SEIS regarding the phased construction of the MLS stadium, ~~it will be used~~ there has not been a need to examine if new significant adverse pedestrian impacts could potentially occur at these locations. ~~Where appropriate, mitigation measures similar to those presented in this Draft SEIS will be explored to address these impacts to the extent practicable, and where pedestrian impacts cannot be feasibly mitigated, they will be disclosed as unmitigatable.~~

Overall Intersection			-	-	16.9	C	-	-	13.0	B	-	-	13.8	B

Notes

- (1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): This table has been revised for the Final SEIS.

Notes
(1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes

- (1): Control delay is measured in seconds per vehicle.
- (2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
- (3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
- (4): This table has been revised for the Final SEIS.

Notes
(1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes

- (1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes
(1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes

- (1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes
(1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.

Notes

- (1): Control delay is measured in seconds per vehicle.
(2): Overall intersection V/C ratio is the critical lane groups' V/C ratio.
(3): V/C ratios above 1.20 represent saturated conditions and, at several locations, result in predicted average vehicle delays in the 1,000 to 4,000+ second range for signalized intersections and 1,000 to 10,000+ second range for unsignalized intersections. These are theoretical HCM-generated outputs that may, in fact, overestimate delays for such conditions. Lane groups reflecting these conditions are presented in the tables as having delays of "1,000+" seconds and v/c ratios of approximately "3.00+".
(4): This table has been revised for the Final SEIS.
